## Prerequisites

 Bookmarked

### Prerequisites

Some familiarity with using JupyterLab Notebooks.

---

## Learning Objectives

 Bookmarked

### Learning Objectives

In this course you will learn about:

- The major steps involved in tackling a data science problem.
- The major steps involved in practicing data science, from forming a concrete business or research problem, to collecting and analyzing data, to building a model, and understanding the feedback after model deployment.
- How data scientists think through tackling interesting real-world examples.

# Syllabus

## Syllabus

### Module 1: From Problem to Approach

- Business Understanding
- Analytic Approach

### Module 2: From Requirements to Collection

- Data Requirements
- Data Collection

### Module 3: From Understanding to Preparation

- Data Understanding
- Data Preparation

## Module 4: From Modeling to Evaluation

- Modeling
- Evaluation

## Module 5: From Deployment to Feedback

- Deployment
- Feedback

## Module 6: Summary and Final Assignment

---

### Grading Scheme

 Bookmarked

#### Grading Scheme

1. The minimum passing mark for the **course** is 70% with the following weights:
  - 90% - All Review Questions
  - 10% - Final Assignment
2. Review Questions have no time limit. You are encouraged to review the course material to find the answers.
3. The final assignment is a peer-review assessment.
4. Attempts are per **question** in the Review Questions:
  - One attempt - For True/False questions
  - Two attempts - For any question other than True/False
5. There are no penalties for incorrect attempts.
6. Clicking the "**Final Check**" button when it appears, means your submission is **FINAL**. You will **NOT** be able to resubmit your answer for that question ever again.
7. Check your grades in the course at any time by clicking on the "Progress" tab.

## Welcome

welcome to data science methodology 101 this is the beginning of a story one  
that you'll be telling others about for years to come it won't be in the form you experiencehere  
but rather through the storiesyou'll be sharing with others as you explain how your  
understanding of a question resulted in an answer that changed the way  
something was done despite the recent increase in computing power and access to data over the  
last couple of decades our ability to use the data within the decision-making process is either  
lost or not maximized as all too often we don't have a solid  
understanding of the questions being asked and how to apply the data correctly to  
the problem at hand here is a definition of the word methodology it's important to consider it  
because all too often there's a temptation to bypass methodology and jump directly to solutions  
doing so however hinders our best intentions in trying to solve the  
problem this course has one purpose and that is to share a methodology that can be used within  
data science to ensure that the data used in problem solving is relevant  
and properly manipulated to address the question at hand the data science methodology  
discussed in this course has been outlined by john rollins a seasoned and senior data  
scientist currently practicing at ibm this course is built on his experience and expresses  
his position on the importance of following a methodology to be successful in a nutshell the data  
science methodology aims to answer 10 basic questions in a prescribed  
sequence as you can see from this slide there are two questions designed to define the  
issue and thus determine the approach to be used then there are four questions that will  
help you get organized around the data you'll need and finally there are four additional  
questions aimed at validating both the data and the approach that gets designed  
please take a moment now to familiarize yourself with the 10 questions  
as they'll be vital to your success this course is comprised of several  
components there are five modules each going through two stages of the  
methodology explaining the rationale as to why each stage is required  
within the same module a case study is shared that supports what you've just  
learned there's also a hands-on lab which helps to apply the material  
and finally there are three review questions to test your understanding of  
the concepts when you're ready take the final exam the case study included in the course  
highlights how the data science methodology can be applied in context

it revolves around the following scenario there's a limited budget for providing health care to the public hospital readmissions for reoccurring problems can be seen as a sign of failure in the system to properly address the patient condition prior to the initial patient discharge the core question is what is the best way to allocate these funds to maximize their use in providing quality care as you'll see if the new data science pilot program is successful it will deliver better patient care by giving physicians new tools to incorporate timely data-driven information into patient care decisions the case study sections display these icons at the top right hand corner of your screen to help you differentiate theory from practice within each module while participating in the course if you come across some challenges or have some questions then please explore the discussion and wiki sessions so now that you're all set adjust your headphones and let's get started.

# Data Science Methodology

---

Welcome

# What is a methodology anyway?

*A methodology is a defined way of....*

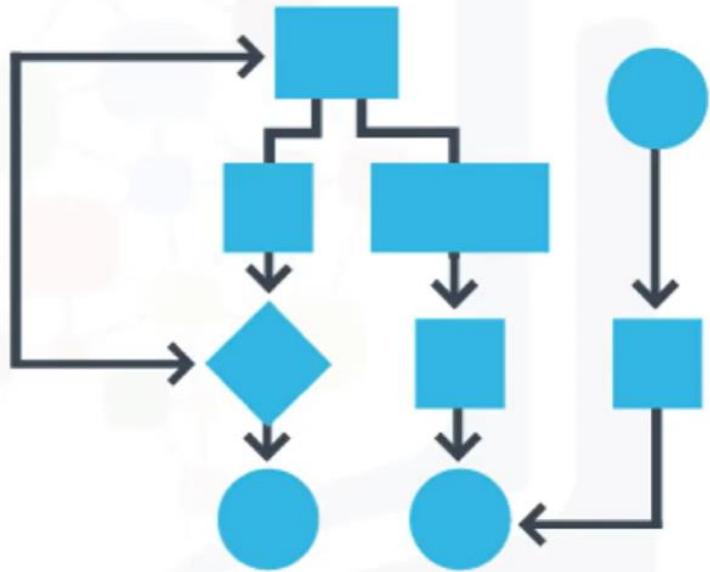

**meth·od·ol·o·gy**

*noun*

noun: **methodology**; plural noun:

**methodologies**

- 1 a system of methods used in a particular area of study or activity.  
“a methodology for investigating the concept of focal points”

# In a nutshell...

The **Data Science Methodology** aims to answer the following 10 questions in this prescribed sequence:

## From problem to approach:

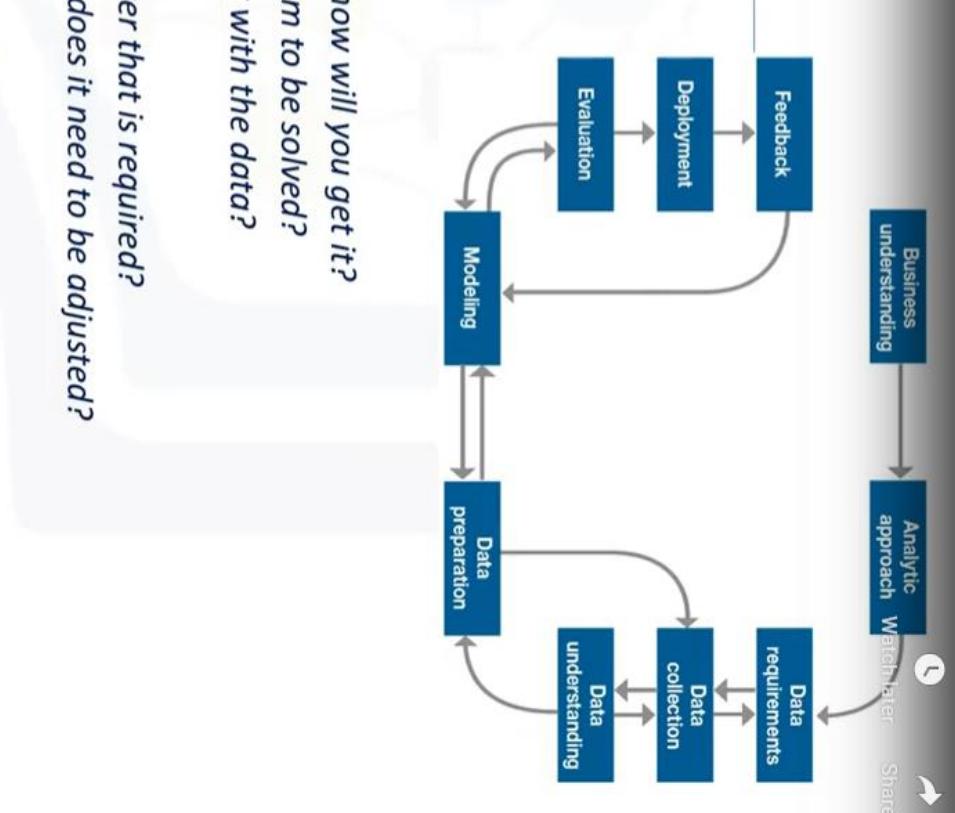

1. What is the problem that you are trying to solve?
2. How can you use data to answer the question?

## Working with the data:

3. What data do you need to answer the question?
4. Where is the data coming from (identify all sources) and how will you get it?
5. Is the data that you collected representative of the problem to be solved?
6. What additional work is required to manipulate and work with the data?

## Deriving the answer:

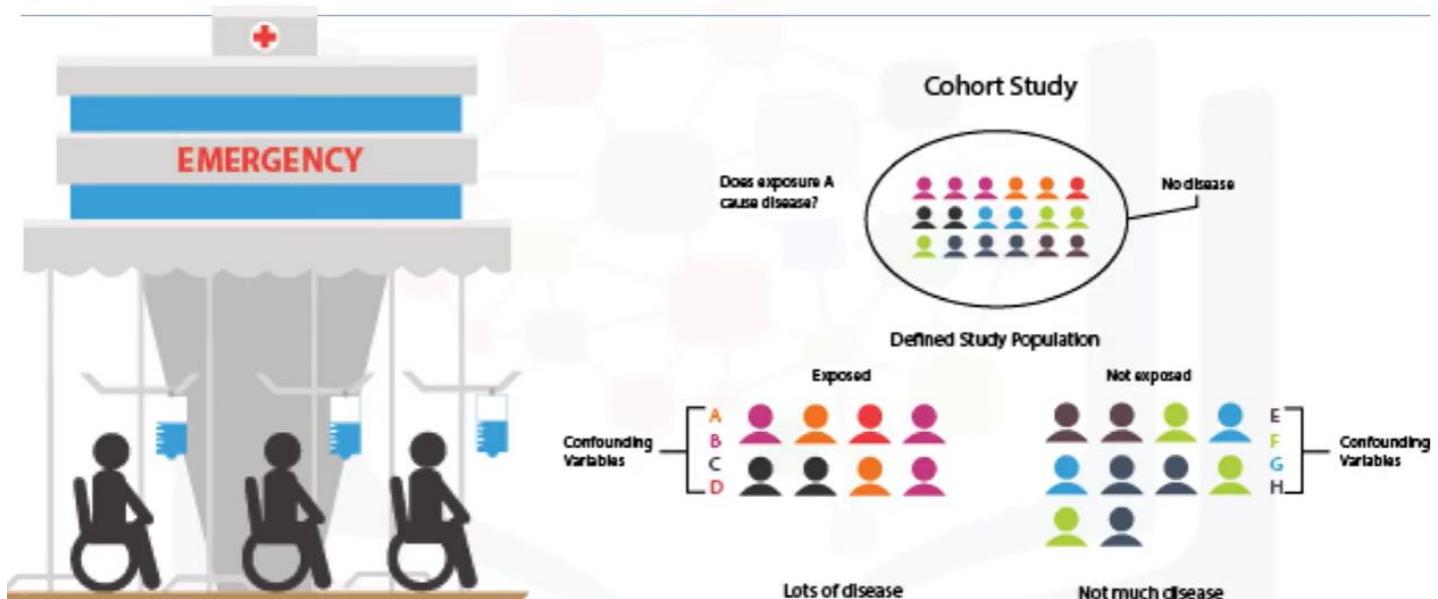

7. In what way can the data be visualized to get to the answer that is required?
8. Does the model used really answer the initial question or does it need to be adjusted?
9. Can you put the model into practice?
10. Can you get constructive feedback into answering the question?

# Course structure

- **Module 1: From Problem to Approach**
  - Business Understanding – Concepts & Case Study
  - Analytic Approach – Concepts & Case Study
  - Hands-on Lab & Review
  
- **Module 2: From Requirements to Collection**
  - Data Requirements – Concepts & Case Study
  - Data Collection – Concepts & Case Study
  - Hands-on Lab & Review
  
- **Module 3: From Understanding to Preparation**
  - Data Understanding – Concepts & Case Study
  - Data Preparation – Concepts
  - Data Preparation – Case Study
  - Hands-on Lab & Review
  
- **Module 4: From Modeling to Evaluation**
  - Modeling – Concepts
  - Modeling – Case Study
  - Evaluation – Concepts & Case Study
  - Hands-on Lab & Review
  
- **Module 5: From Deployment to Feedback**
  - Deployment – Concepts & Case Study
  - Feedback – Concepts & Case Study
  - Hands-on Lab & Review

## Your participation

# Data Science Methodologies

This course focuses on the Foundational Methodology for Data Science by John Rollins, which was introduced in the previous video. However, it is not the only methodology that you will encounter in data science. For example, in data mining, the [Cross Industry Process for Data Mining \(CRISP-DM\)](#) methodology is widely used.

## What is CRISP-DM?

The CRISP-DM methodology is a process aimed at increasing the use of data mining over a wide variety of business applications and industries. The intent is to take case specific scenarios and general behaviors to make them domain neutral. CRISP-DM is comprised of six steps with an entity that has to implement in order to have a reasonable chance of success. The six steps are shown in the following diagram:

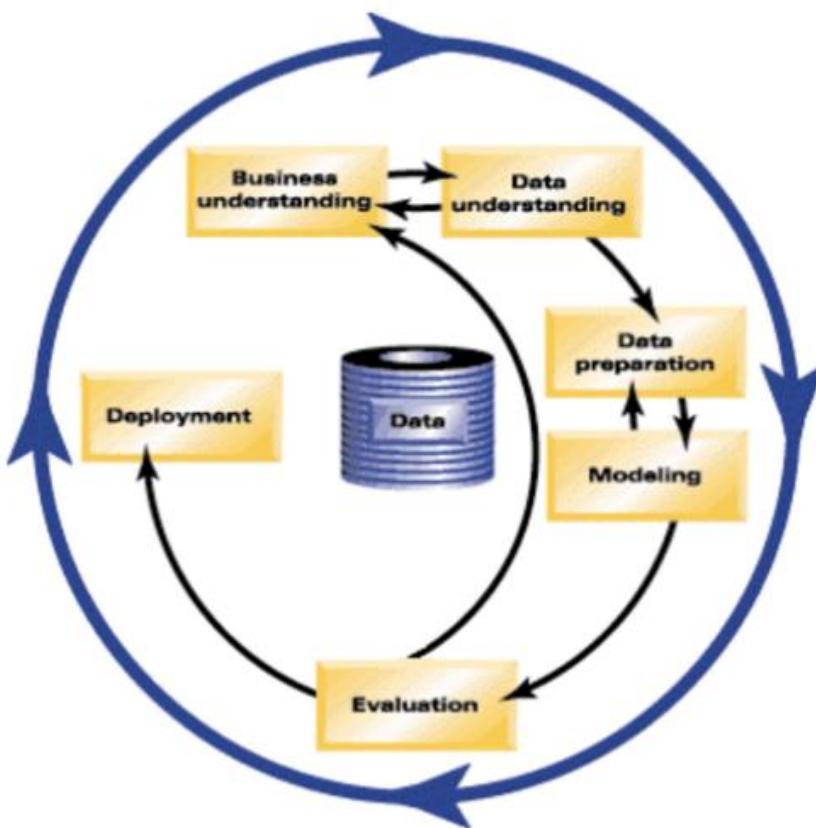

Fig.1 CRISP-DM model, [IBM Knowledge Center, CRISP-DM Help Overview](#)

## **1. Business Understanding:**

This stage is the most important because this is where the intention of the project is outlined. Foundational Methodology and CRISP-DM are aligned here. It requires communication and clarity. The difficulty here is that stakeholders have different objectives, biases, and modalities of relating information. They don't all see the same things or in the same manner. Without clear, concise, and complete perspective of what the project goals are resources will be needlessly expended.

## **2. Data Understanding:**

Data understanding relies on business understanding. Data is collected at this stage of the process. The understanding of what the business wants and needs will determine what data is collected, from what sources, and by what methods. CRISP-DM combines the stages of Data Requirements, Data Collection, and Data Understanding from the Foundational Methodology outline.

## **3. Data Preparation:**

Once the data has been collected, it must be transformed into a useable subset unless it is determined that more data is needed. Once a dataset is chosen, it must then be checked for questionable, missing, or ambiguous cases. Data Preparation is common to CRISP-DM and Foundational Methodology.

## **4. Modeling:**

Once prepared for use, the data must be expressed through whatever appropriate models, give meaningful insights, and hopefully new knowledge. This is the purpose of data mining: to create knowledge information that has meaning and utility. The use of models reveals patterns and structures within the data that provide insight into the features of interest. Models are selected on a portion of the data and adjustments are made if necessary. Model selection is an art and science. Both Foundational Methodology and CRISP-DM are required for the subsequent stage.

## **5. Evaluation**

The selected model must be tested. This is usually done by having a pre-selected test, set to run the trained model on. This will allow you to see the effectiveness of the model on a set it sees as new. Results from this are used to determine efficacy of the model and foreshadows its role in the next and final stage.

## **6. Deployment:**

In the deployment step, the model is used on new data outside of the scope of the dataset and by new stakeholders. The new interactions at this phase might reveal the new variables and needs for the dataset and model. These new challenges could initiate revision of either business needs and actions, or the model and data, or both.

CRISP-DM is a highly flexible and cyclical model. Flexibility is required at each step along with communication to keep the project on track. At any of the six stages, it may be necessary to revisit an earlier stage and make changes. The key point of this process is that it's cyclical; therefore, even at the finish you are having another business understanding encounter to discuss the viability after deployment. The journey continues.

## Learning Objectives

■ Bookmarked

### Learning Objectives

In this module you will:

- Learn about why we are interested in data science.
- Learn what a methodology is, and why data scientists need a methodology.
- Learn about the data science methodology and its flowchart.
- Learn about the Business Understanding and the Analytic Approach stages of the data science methodology.
- Learn how to complete the Business Understanding and the Analytic Approach stages pertaining to any data science problem.

## Business Understanding

Welcome to Data Science Methodology 101 From Problem to Approach Business Understanding!

Has this ever happened to you?

You've been called into a meeting by your boss, who makes you aware of an important task one with a very tight deadline that absolutely has to be met.

You both go back and forth to ensure that all aspects of the task have been considered

and the meeting ends with both of you confident that things are on track.

Later that afternoon, however, after you've spent some time examining the various issues at play, you realize that you need to ask several additional questions in order to truly accomplish the task.

Unfortunately, the boss won't be available again until tomorrow morning.

Now, with the tight deadline still ringing in your ears, you start feeling a sense of uneasiness. So, what do you do?

Do you risk moving forward or do you stop and seek clarification.

Data science methodology begins with spending the time to seek clarification, to attain what can be referred to as a business understanding.

Having this understanding is placed at the beginning of the methodology because getting clarity around the problem to be solved, allows you to determine which data will be used to answer the core question.

Rollins suggests that having a clearly defined question is vital because it ultimately directs the analytic approach that will be needed to address the question.

All too often, much effort is put into answering what people THINK is the question, and while the methods used to address that question might be sound, they don't help to solve the actual problem.

Establishing a clearly defined question starts with understanding the GOAL of the person who is asking the question.

For example, if a business owner asks: "How can we reduce the costs of performing an activity?" We need to understand, is the goal to improve the efficiency of the activity?

Or is it to increase the businesses profitability?

Once the goal is clarified, the next piece of the puzzle is to figure out the objectives that are in support of the goal.

By breaking down the objectives, structured discussions can take place where priorities can be identified in a way that can lead to organizing and planning on how to tackle the problem. Depending on the problem, different stakeholders will need to be engaged in the discussion to help determine requirements and clarify questions.

So now, let's look at the case study related to applying "Business Understanding"

In the case study, the question being asked is: What is the best way to allocate the limited healthcare budget to maximize its use in providing quality care?

This question is one that became a hot topic for an American healthcare insurance provider. As public funding for readmissions was decreasing, this insurance company was at risk of having to make up for the cost difference, which could potentially increase rates for its customers.

Knowing that raising insurance rates was not going to be a popular move, the insurance company sat down with the health care authorities in its region and brought in IBM data scientists to see how data science could be applied to the question at hand.

Before even starting to collect data, the goals and objectives needed to be defined.

After spending time to determine the goals and objectives, the team prioritized "patient readmissions" as an effective area for review. With the goals and objectives in mind, it was found that approximately 30% of individuals who finish rehab treatment would be readmitted to a rehab center within one year; and that 50% would be readmitted within five years.

After reviewing some records, it was discovered that the patients with congestive heart failure were at the top of the readmission list. It was further determined that a decision-tree model could be applied to review this scenario, to determine why this was occurring.

To gain the business understanding that would guide the analytics team in formulating and performing their first project, the IBM Data scientists, proposed and delivered an on-site workshop to kick things off.

The key business sponsors involvement throughout the project was critical, in that the sponsor:

Set overall direction

Remained engaged and provided guidance.

Ensured necessary support, where needed.

Finally, four business requirements were identified for whatever model would be built.

Namely:

Predicting readmission outcomes for those patients with Congestive Heart Failure

Predicting readmission risk.

Understanding the combination of events that led to the predicted outcome

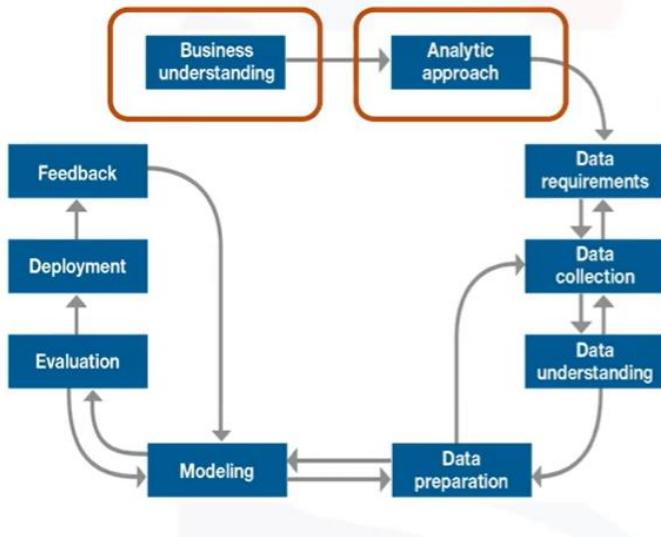

Applying an easy-to-understand process to new patients, regarding their readmission risk.

This ends the Business Understanding section of this course.

# The Importance of Questions

## From Understanding to Approach

### Business understanding

- *What is the problem that you are trying to solve?*

### Analytic approach

- *How can you use data to answer the question?*

Seeking clarification – What's the goal?

## Supporting the Goal

## Getting stakeholder “buy-in” and support

## Case Study – Applying the concepts

Watch later

# Case Study

UTU3EN Module 1 Business Understanding

## Case Study – Applying the concepts

What is the best way to allocate the limited healthcare budget to maximize its use in providing quality care?

# Case Study – What are the goals & objectives?

## Define the GOALS

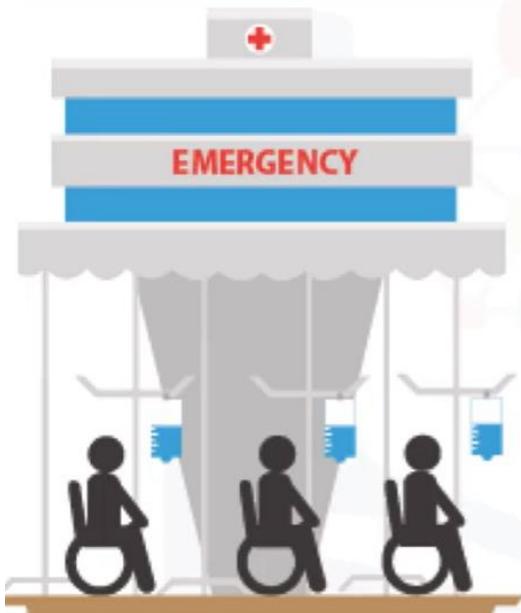

- To provide quality care without increasing costs

## Define the OBJECTIVES

- To review the process to identify inefficiencies

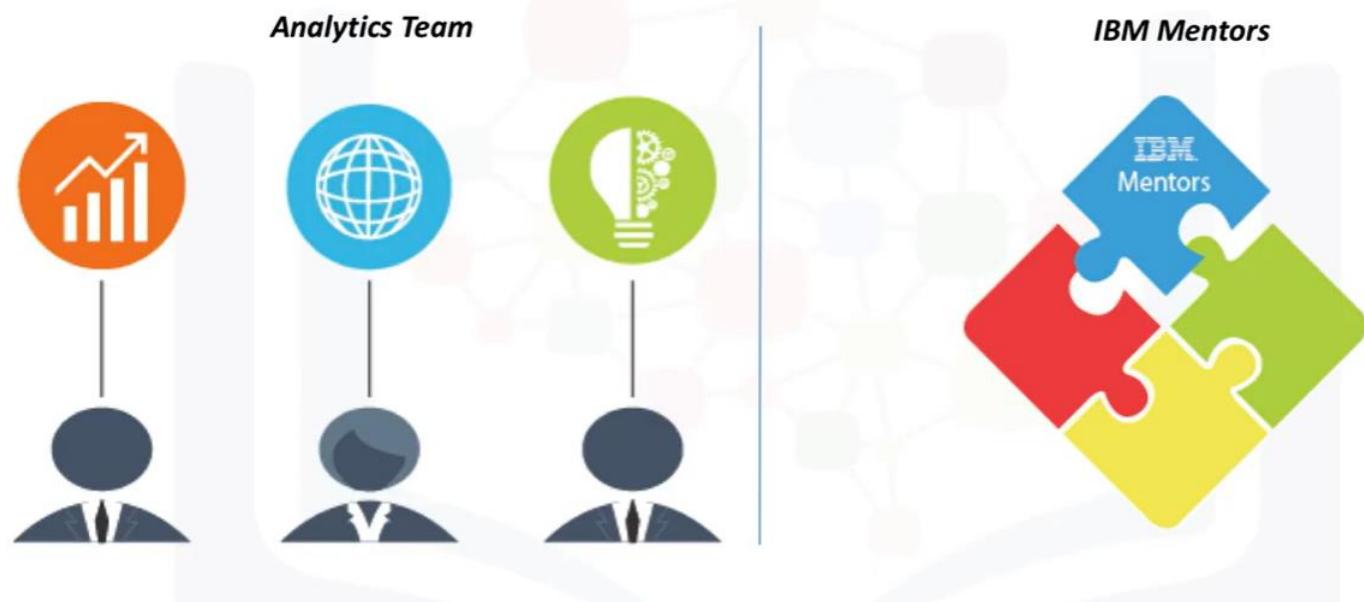

# Case Study – Examining Hospital Readmissions

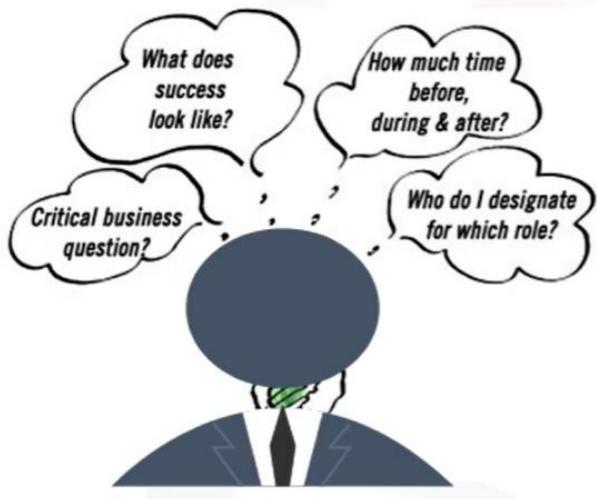

Roughly 25-35% of patients who complete rehab treatment will be readmitted to a rehabilitation center within one year and roughly 50% will be readmitted within five years.

# Case Study – Pilot project kickoff

## Case Study – What's the sponsor's involvement?

1. Set overall direction
2. Remained engaged and provide guidance
3. Ensured necessary support, where needed

# Case Study – Identifying the business requirements

1. Predict CHF readmission outcome (Y or N) for each patient
2. Predict the readmission risk for each patient
3. Understand explicitly what combination of events led to the predicted outcome for each patient
4. Easy to understand and apply to new patients to predict their readmission risk

## Analytic Approach

Welcome to Data Science Methodology 101 From problem to approach Analytic Approach!

Selecting the right analytic approach depends on the question being asked.

The approach involves seeking clarification from the person who is asking the question, so as to be able to pick the most appropriate path or approach.

In this video we'll see how the second stage of the data science methodology is applied.

Once the problem to be addressed is defined, the appropriate analytic approach for the problem is selected in the context of the business requirements.

This is the second stage of the data science methodology.

Once a strong understanding of the question is established, the analytic approach can be selected.

This means identifying what type of patterns will be needed to address the question most effectively.

If the question is to determine probabilities of an action, then a predictive model might be used.

If the question is to show relationships, a descriptive approach maybe be required.

This would be one that would look at clusters of similar activities based on events and preferences.

Statistical analysis applies to problems that require counts. For example if the question requires a yes/ no answer, then a classification approach

to predicting a response would be suitable.

Machine Learning is a field of study that gives computers the ability to learn without being explicitly programmed. Machine Learning can be used to identify relationships and trends in data that might otherwise not be accessible or identified.

In the case where the question is to learn about human behaviour, then an appropriate response would be to use Clustering Association approaches.

So now, let's look at the case study related to applying Analytic Approach.

For the case study, a decision tree classification model was used to identify the combination of conditions leading to each patient's outcome.

In this approach, examining the variables in each of the nodes along each path to a leaf, led to a respective threshold value. This means the decision tree classifier provides both the predicted outcome, as well as the

likelihood of that outcome, based on the proportion at the dominant outcome, yes or no, in each group.

From this information, the analysts can obtain the readmission risk, or the likelihood of a yes for each patient. If the dominant outcome is yes, then the risk is simply the proportion of yes patients in the leaf.

If it is no, then the risk is 1 minus the proportion of no patients in the leaf.

A decision tree classification model is easy for non-data scientists to understand and apply, to score new patients for their risk of readmission.

Clinicians can readily see what conditions are causing a patient to be scored as high-risk and multiple models can be built and applied at various points during hospital stay.

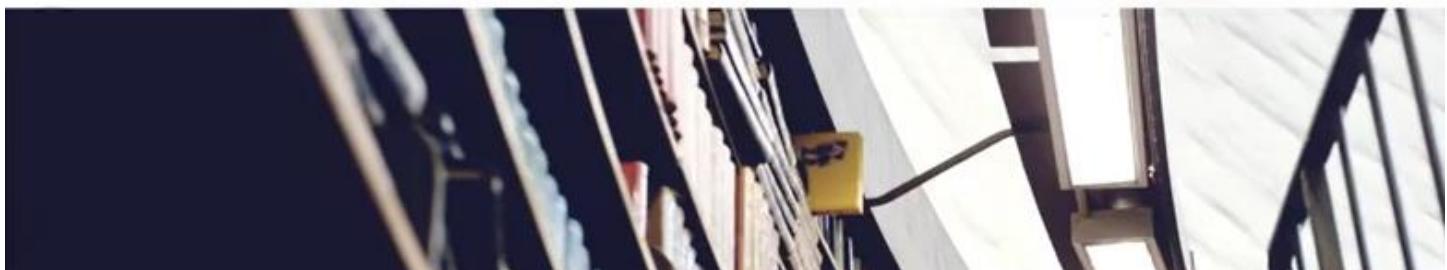

This gives a moving picture of the patient's risk and how it is evolving with the various treatments being applied. For these reasons, the decision tree classification approach was chosen for building the Congestive Heart Failure readmission model.

# Data Science Methodology

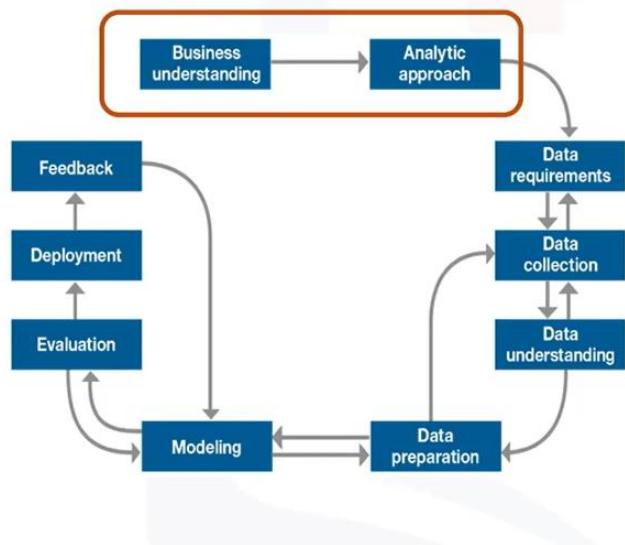

## Analytic Approach

S0105EN Module 1 Analytic Approach

### Which analytic approach to pick?

### From Understanding to Approach

#### Business understanding

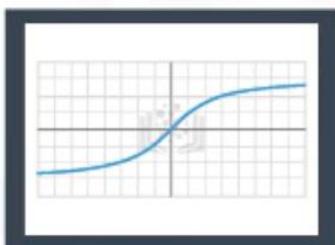

- *What is the problem that you are trying to solve?*

#### Analytic approach

- *How can you use data to answer the question?*

# Pick analytic approach based on type of question

## Descriptive

- Current status

## Diagnostic (Statistical Analysis)

- What happened?
- Why is this happening?

## Predictive (Forecasting)

- What if these trends continue?
- What will happen next?

## Prescriptive

- How do we solve it?

DS0103EN Module 1 Analytic Approach

## What are the types of questions?

### If the question is to determine probabilities of an action

- Use a Predictive model

### If the question is to show relationships

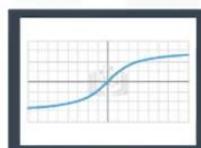

- Use a descriptive model

### If the question requires a yes/no answer

- Use a classification model

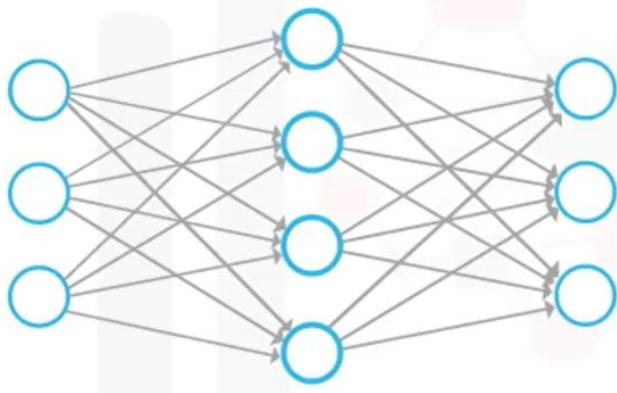

### Analytic approach

- *How can you use data to answer the question?*

- The correct approach depends on business requirements for the model

# Will machine learning be utilized?

## Machine Learning

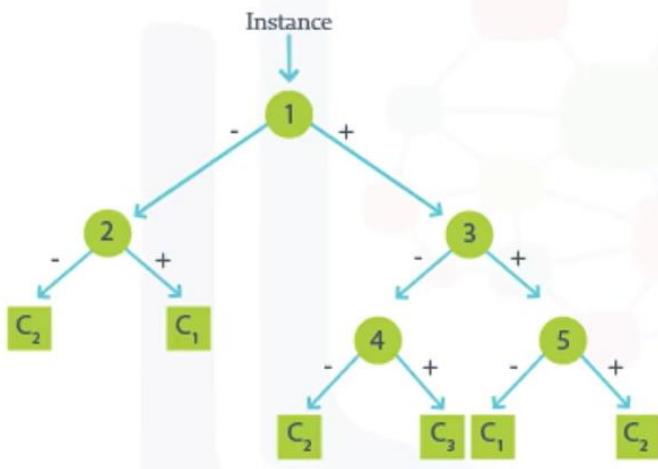

- Learning without being explicitly programmed
- Identifies relationships and trends in data that might otherwise not be accessible or identified
- Uses clustering association approaches

# Case Study – Applying the concepts

## Case Study

# Case Study – Decision tree classification selected!

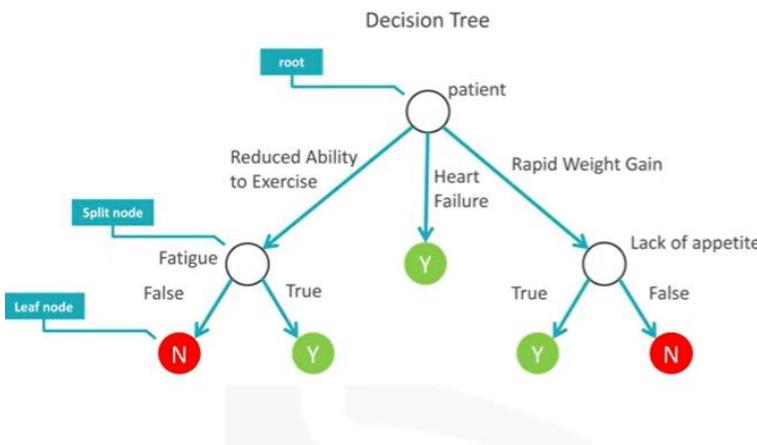

## Predictive model

- To predict an outcome

## Decision tree classification

- Categorical outcome
- Explicit “decision path” showing conditions leading to high risk
- Likelihood of classified outcome
- Easy to understand and apply

# Case Study – Example of decision tree classification

## Predictive model

- To predict an outcome

## Decision tree classification

- Categorical outcome
- Explicit “decision path” showing conditions leading to high risk
- Likelihood of classified outcome
- Easy to understand and apply

Skills Network Labs (SN Labs) is a virtual lab environment used in this course. Upon clicking the "Start Lab" button, you will be prompted to have your Username and Email passed to Skills Network Labs in accordance with the IBM Skills Network privacy policy, and will only be used for communicating important information to enhance your learning experience.

[Start Lab !\[\]\(72b4cf351241b08691672e806c1604b7\_img.jpg\)](#)

SN Labs provides a Cloud-based virtual lab environment to help you complete hands-on labs for this course without the need to download, install and configure software like Jupyter on your computer. However, if you are having issues using SN Labs, or prefer to use JupyterLab on your own computer you can [download the notebook](#) file for this lab.

## From Problem to Approach

Estimated time needed: **20** minutes

### Objectives

After completing this lab you will be able to:

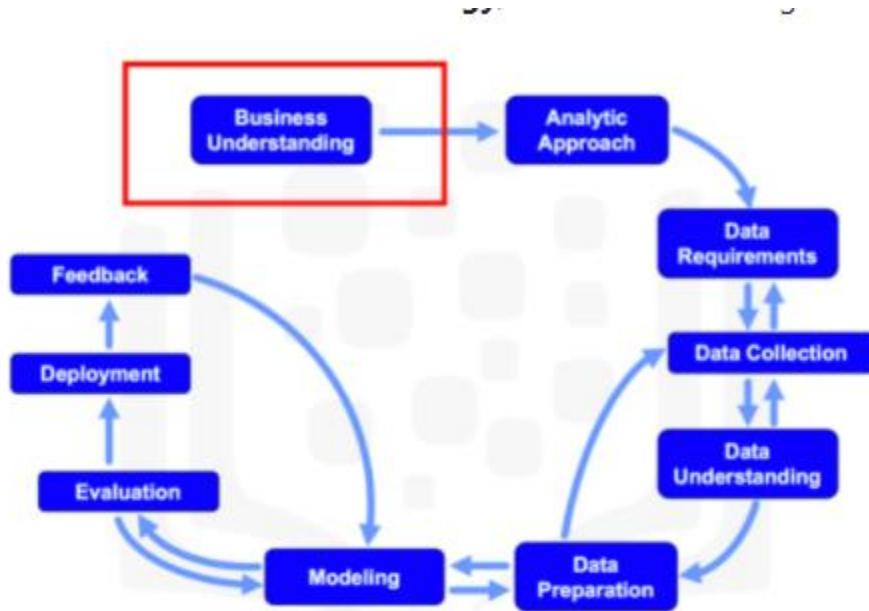

- Have a Business Understanding of case studies
- Analytically approach problems

# Table of Contents

1. Business Understanding
2. Analytic Approach

## Business Understanding

This is the **Data Science Methodology**, a flowchart that begins with business understanding.

Why is the business understanding stage important?

Why is the business understanding stage important?

Your Answer:

The business understanding stage is important because this is where the intention of the project is outlined.

▼ Click here for the solution

#The correct answer is:

It helps clarify the goal of the entity asking the question.

Looking at this diagram, we immediately spot two outstanding features of the data science methodology.

What are they?

Your Answer:

- 1.Iterative
- 2.flowchart has no end.

▼ Click here for the solution

#The correct answer is:

- # 1. The flowchart is highly iterative.
- #2. The flowchart never ends.

Now let's illustrate the data science methodology with a case study.

Say, we are interested in automating the process of figuring out the cuisine of a given dish or recipe. Let's apply the business understanding stage to this problem.

Q. Can we predict the cuisine of a given dish using the name of the dish only?

Your Answer:  
No

▼ Click here for the solution

#The correct answer is:

No.

Q. For example, the following dish names were taken from the menu of a local restaurant in Toronto, Ontario in Canada.

1. Beast
2. 2 PM
3. 4 Minute

Are you able to tell the cuisine of these dishes?

Your Answer:  
1. Beast is Japanese.  
2.  
3.

▼ Click here for the solution  
*#The correct answer is:*  
 The cuisine is **Japanese**. Here are links to the images of the dishes:  
 Beast: <https://ibm.box.com/shared/static/5e7duvewfl5bk4317sna5skvdhrehro2.png>  
 2PM: <https://ibm.box.com/shared/static/d9xuzqm8cq76zxcc0f9gdt4iksiyk.png>  
 4 Minute: <https://ibm.box.com/shared/static/f1fwvvvn4u8rx8tghep6zyj5pi6a8v8k.png>  
 Photographs by Avlxyz: [https://commons.wikimedia.org/wiki/Category:Photographs\\_by\\_Avlxyz](https://commons.wikimedia.org/wiki/Category:Photographs_by_Avlxyz)

Q. What about by appearance only? Yes or No.

Your Answer:  
 No

▼ Click here for the solution  
*#The correct answer is:*  
 No, especially when it comes to countries in close geographical proximity such as Scandinavian countries, or Asian countries.

At this point, we realize that automating the process of determining the cuisine of a given dish is not a straightforward problem as we need to come up with a way that is very robust to the many cuisines and their variations.

Q. What about determining the cuisine of a dish based on its ingredients?

Your Answer:  
 Yes

▼ Click here for the solution  
*#The correct answer is:*  
 Potentially yes, as there are specific ingredients unique to each cuisine.

As you guessed, yes determining the cuisine of a given dish based on its ingredients seems like a viable solution as some ingredients are unique to cuisines. For example:

- When we talk about **American** cuisines, the first ingredient that comes to one's mind (or at least to my mind =D) is beef or turkey.
- When we talk about **British** cuisines, the first ingredient that comes to one's mind is haddock or mint sauce.
- When we talk about **Canadian** cuisines, the first ingredient that comes to one's mind is bacon or poutine.
- When we talk about **French** cuisines, the first ingredient that comes to one's mind is bread or butter.
- When we talk about **Italian** cuisines, the first ingredient that comes to one's mind is tomato or ricotta.
- When we talk about **Japanese** cuisines, the first ingredient that comes to one's mind is seaweed or soy sauce.
- When we talk about **Chinese** cuisines, the first ingredient that comes to one's mind is ginger or garlic.
- When we talk about **Indian** cuisines, the first ingredient that comes to one's mind is masala or chillis.

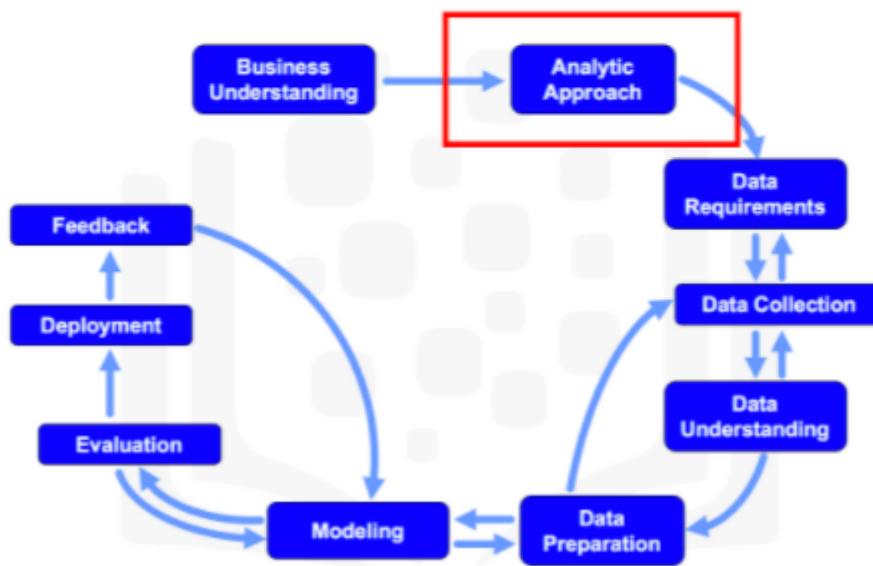

Your Answer:  
sushi roll

▼ Click here for the solution

#The correct answer is:

Japanese since the recipe is most likely that of a sushi roll.

## Analytic Approach

### So why are we interested in data science?

Once the business problem has been clearly stated, the data scientist can define the analytic approach to solve the problem. This step entails expressing the problem in the context of statistical and machine-learning techniques, so that the entity or stakeholders with the problem can identify the most suitable techniques for the desired outcome.

Why is the analytic approach stage important?

Your Answer:

helps identify what type of patterns will be needed to address the question most effectively

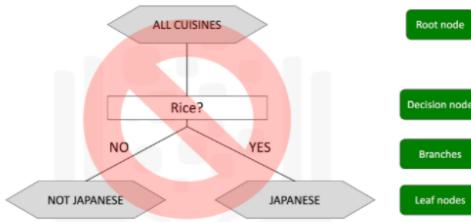

▼ Click here for the solution

#The correct answer is:

Because it helps identify what type of patterns will be needed to address the question most effectively.

Let's explore a machine learning algorithm, decision trees, and see if it is the right technique to automate the process of identifying the cuisine of a given dish or recipe while simultaneously providing us with some insight on why a given recipe is believed to belong to a certain type of cuisine.

This is a decision tree that a naive person might create manually. Starting at the top with all the recipes for all the cuisines in the world, if a recipe contains **rice**, then this decision tree would classify it as a **Japanese** cuisine. Otherwise, it would be classified as not a **Japanese** cuisine.

Is this a good decision tree? Yes or No, and why?

Your Answer:  
No because there lots of dishes that contain rice. |

▼ Click here for the solution

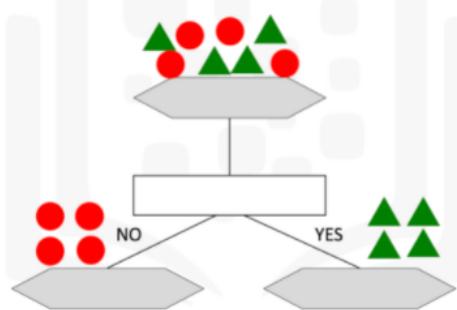

#The correct answer is:  
No, because a plethora of dishes from other cuisines contain rice. Therefore, using rice as the ingredient in the Decision node to split on is not a good choice.

In order to build a very powerful decision tree for the recipe case study, let's take some time to learn more about decision trees.

- Decision trees are built using recursive partitioning to classify the data.
- When partitioning the data, decision trees use the most predictive feature (ingredient in this case) to split the data.
- **Predictiveness** is based on decrease in entropy - gain in information, or *impurity*.

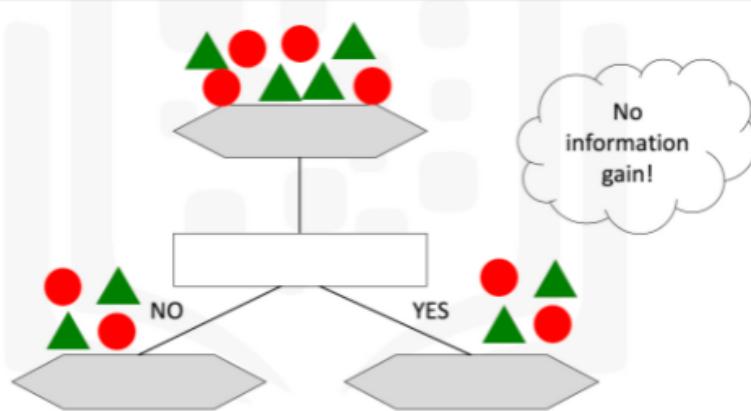

Suppose that our data is comprised of green triangles and red circles.

The following decision tree would be considered the optimal model for classifying the data into a node for green triangles and a node for red circles.

Each of the classes in the leaf nodes are completely pure – that is, each leaf node only contains datapoints that belong to the same class.

On the other hand, the following decision tree is an example of the worst-case scenario that the model could output.

Each leaf node contains datapoints belonging to the two classes resulting in many datapoints ultimately being misclassified.

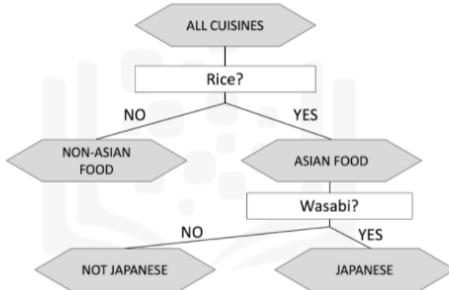

A tree stops growing at a node when:

- Pure or nearly pure.
- No remaining variables on which to further subset the data.
- The tree has grown to a preselected size limit.

Here are some characteristics of decision trees:

Pros	Cons
Easy to interpret	Easy to overfit or underfit the model
Can handle numeric or categorical features	Cannot model interactions between features
Can handle missing data	Large trees can be difficult to interpret
Uses only the most important features	
Can be used on very large or small data	

Now let's put what we learned about decision trees to use. Let's try and build a much better version of the decision tree for our recipe problem.

I hope you agree that the above decision tree is a much better version than the previous one. Although we are still using **Rice** as the ingredient in the first *decision node*, recipes get divided into **Asian Food** and **Non-Asian Food**. **Asian Food** is then further divided into **Japanese** and **Not Japanese** based on the **Wasabi** ingredient. This process of splitting *leaf nodes* continues until each *leaf node* is pure, i.e., containing recipes belonging to only one cuisine.

Accordingly, decision trees is a suitable technique or algorithm for our recipe case study.

**Thank you for completing this lab!**

This notebook was created by Alex Akson. I hope you found this lab session interesting. Feel free to contact me if you have any questions!

This notebook is part of a course called *The Data Science Method*. If you accessed this notebook outside the course, you can take this course, online by clicking [here](#).

## Module Summary

In this module, you have learned:

- The need to understand and prioritize the business goal.
- The way stakeholder support influences a project.
- The importance of selecting the right model.
- When to use a predictive, descriptive, or classification model.

## Graded Review Questions

Quiz due Dec 5, 2021 18:39 CST

### Instructions for Review Questions

1. Time allowed: **Unlimited**

- We encourage you to go back and review the materials to find the right answer
- Please remember that the Review Questions are worth 60% of your final mark.

2. Attempts per question:

- One attempt - For True/False questions
- Two attempts - For any question other than True/False

3. Clicking the "**Final Check**" button when it appears, means your submission is **FINAL**. You will **NOT** be able to resubmit your answer for that question ever again

4. Check your grades in the course at any time by clicking on the "Progress" tab

## Question 1

1/1 point (graded)

Select the correct statement.

- The data science methodology described in this course is limited to IBM.
- The data science methodology described in this course is outlined by John Rollins from IBM.
- The data science methodology described in this course is only used by certified data scientists.
- None of the above statements are correct.

### Answer

Correct: Correct

[Submit](#)

You have used 2 of 2 attempts

[Show answer](#)

- Correct (1/1 point)

## Question 2

1/1 point (graded)

Select the correct statement.

- The first stage of the data science methodology is Business Understanding.
- The first stage of the data science methodology is Modeling.
- The first stage of the data science methodology is Data Understanding.
- The first stage of the data science methodology is Data Collection.

### Answer

Correct: Correct

[Submit](#)

You have used 1 of 2 attempts

[Save](#) | [Show answer](#)

- Correct (1/1 point)

### Question 3

1/1 point (graded)

Business Understanding is an important stage in the data science methodology. Why?

Because it clearly defines the problem and the needs from a business perspective.

Because it is determined by the analytic approach you want to use.

Because it ensures that the work generates all possible solutions.

Because it generates the data that will be used in the study.

#### Answer

Correct:

Correct, Business understanding allows you to gain clarity about the question being asked, and why it is being asked. Having a clear question is vital, because it determines which analytic approach is needed to address the question.

✓ Correct (1/1 point)

## Module 2 – Data Requirements

Welcome to Data Science Methodology 101 From Requirements to Collection Data Requirements!

If your goal is to make a spaghetti dinner but you don't have the right ingredients to make this dish, then your success will be compromised.

Think of this section of the data science methodology as cooking with data.

Each step is critical in making the meal.

So, if the problem that needs to be resolved is the recipe, so to speak, and data is an ingredient, then the data scientist needs to identify:

which ingredients are required, how to source or collect them,

how to understand or work with them, and how to prepare the data to meet the desired outcome.

**Building on the understanding of the problem at hand, and then using the analytical approach selected, the Data Scientist is ready to get started.**

**Now let's look at some examples of the data requirements within the data science methodology.**

**Prior to undertaking the data collection and data preparation stages of the methodology, it's vital to define the data requirements for decision-tree classification.**

This includes identifying the necessary data content, formats and sources for initial data collection.

So now, let's look at the case study related to applying "Data Requirements".

In the case study, the first task was to define the data requirements for the decision tree classification approach that was selected.

This included selecting a suitable patient cohort from the health insurance providers member base.

In order to compile the complete clinical histories, three criteria were identified for inclusion in the cohort.

First, a patient needed to be admitted as in-patient within the provider service area, so they'd have access to the necessary information.

Second, they focused on patients with a primary diagnosis of congestive heart failure during one full year.

Third, a patient must have had continuous enrollment for at least six months, prior to the primary admission for congestive heart failure, so that complete medical history could be compiled.

Congestive heart failure patients who also had been diagnosed as having other significant medical conditions, were excluded from the cohort because those conditions would cause higher-than-average re-admission rates and, thus, could skew the results.

Then the content, format, and representations of the data needed for decision tree classification were defined.

This modeling technique requires one record per patient, with columns representing the variables in the model.

To model the readmission outcome, there needed to be data covering all aspects of the patient's clinical history.

This content would include admissions, primary, secondary, and tertiary diagnoses, procedures, prescriptions, and other services provided either during hospitalization or throughout patient/doctor visits.

Thus, a particular patient could have thousands of records, representing all their related attributes.

To get to the one record per patient format, the data scientists rolled up the transactional records to the patient level, creating a number of new variables to represent that information.

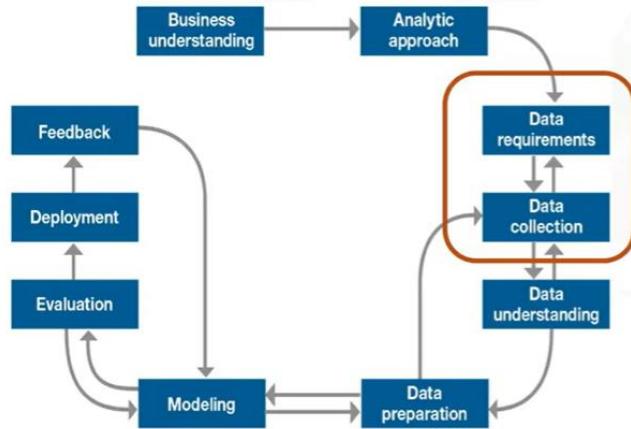

This was a job for the data preparation stage, so thinking ahead and anticipating subsequent

stages is important.

# Data requirements – Cooking with data

Watch later Share

## From Requirements to Collection

### Data Requirements

- What are data requirements?

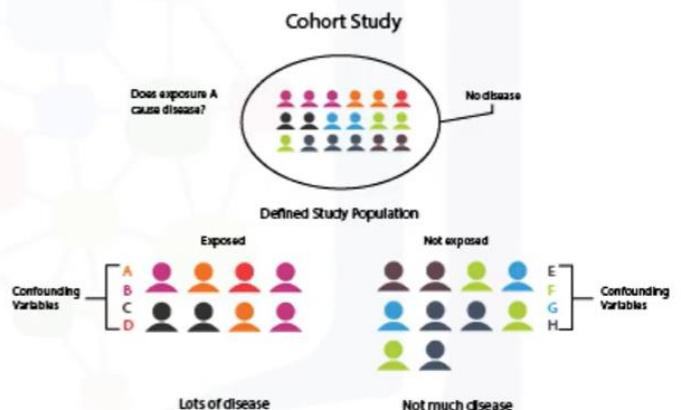

### Data Collection

- What occurs during data collection?

## Case Study – Selecting the cohort

### Define and select cohort

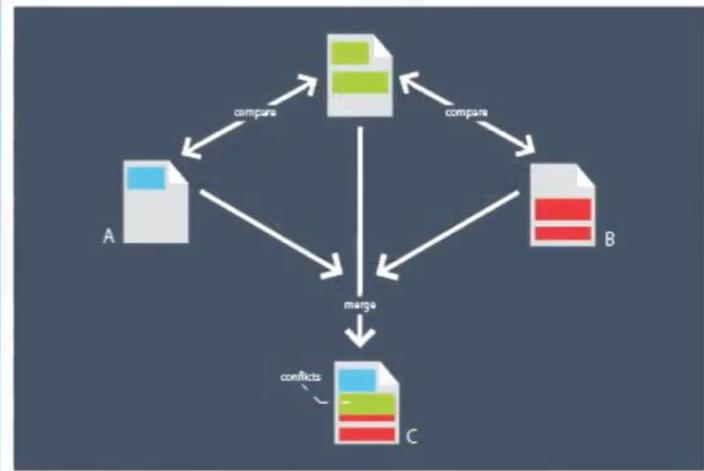

- In-patient within health insurance provider's service area
- Primary diagnosis of CHF in one year
- Continuous enrollment for at least 6 months prior to primary CHF admission
- Disqualifying conditions

# Case Study – Defining the data

- Content, formats, representations suitable for decision tree classifier
  - One record per patient with columns representing variables (dependent variable and predictors)
  - Content covering all aspects of each patient's clinical history
    - Transactional format
    - Transformations required

## Data Collection

After the initial data collection is performed, an assessment by the data scientist takes place to determine whether or not they have what they need.

As is the case when shopping for ingredients to make a meal, some ingredients might be out of season and more difficult to obtain or cost more than initially thought.

In this phase the data requirements are revised and decisions are made as to whether or not the collection requires more or less data.

Once the data ingredients are collected, then in the data collection stage, the data scientist will have a good understanding of what they will be working with.

Techniques such as descriptive statistics and visualization can be applied to the data set, to assess the content, quality, and initial insights about the data.

Gaps in data will be identified and plans to either fill or make substitutions will have to be made.

In essence, the ingredients are now sitting on the cutting board.

Now let's look at some examples of the data collection stage within the data science methodology.

This stage is undertaken as a follow-up to the data requirements stage.

So now, let's look at the case study related to applying "Data Collection".

Collecting data requires that you know the source or, know where to find the data elements that are needed.

In the context of our case study, these can include:

demographic, clinical and coverage information of patients,

provider information, claims records, as well as

pharmaceutical and other information related to all the diagnoses of the congestive heart failure patients.

For this case study, certain drug information was also needed, but that data source was not yet integrated with the rest of the data sources.

This leads to an important point: It is alright to defer decisions about unavailable data, and attempt to acquire it at a later stage.

For example, this can even be done after getting some intermediate results from the predictive modeling.

If those results suggest that the drug information might be important in obtaining a good model, then the time to try to get it would be invested.

As it turned out though, they were able to build a reasonably good model without this drug information.

DBAs and programmers often work together to extract data from various sources, and then merge it.

This allows for removing redundant data, making it available for the next stage of the methodology,

which is data understanding.

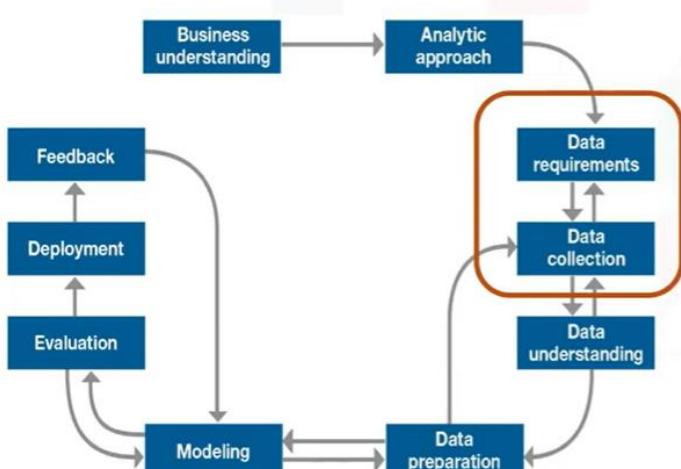

At this stage, if necessary, data scientists and analytics team members can discuss various ways to better manage their data, including automating certain processes in the database, so that

## Lab Instructions

This course uses **Skills Network (SN) Labs**, an online virtual lab environment to help you get hands-on experience without the hassle of installing and configuring the tools. You will get access to popular open-source data science tools like **JupyterLab Notebooks**.

### How to start the hands-on session for this module:

Click the **Start Lab** button below, follow the instructions in the Notebook and start learning! :)

### **From Requirements to Collection (External resource)**

Skills Network Labs (SN Labs) is a virtual lab environment used in this course. Upon clicking the "Start Lab" button, you will be prompted to have your Username and Email passed to Skills Network Labs in accordance with the IBM Skills Network privacy policy, and will only be used for communicating important information to enhance your learning experience.

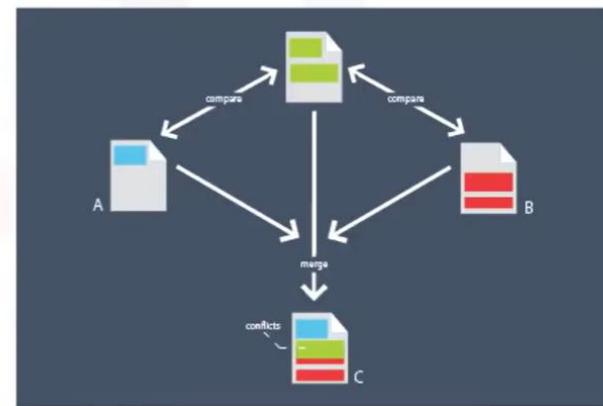

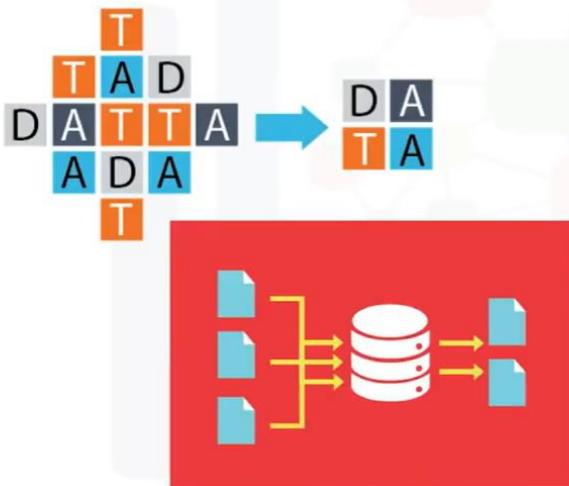

[Start Lab](#) ↗

SN Labs provides a Cloud-based virtual lab environment to help you complete hands-on labs for this course without the need to download, install and configure software like Jupyter on your computer. However, if you are having issues using SN Labs, or prefer to use JupyterLab on your own computer you can [download the notebook file](#) for this lab.

## Case Study – Merging data

- Eliminate redundant data

## From Requirements to Collection

Estimated time needed: **15** minutes

### Objectives

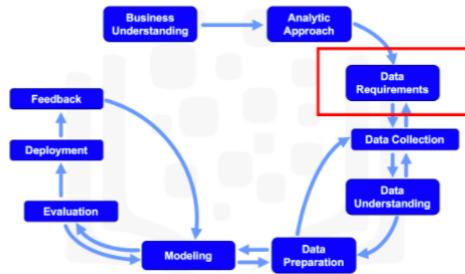

After completing this lab you will be able to:

- Understand Data Requirements
- Explore the stages in Data Collection

### Table of Contents

1. Data Requirements
2. Data Collection

## Data Requirements

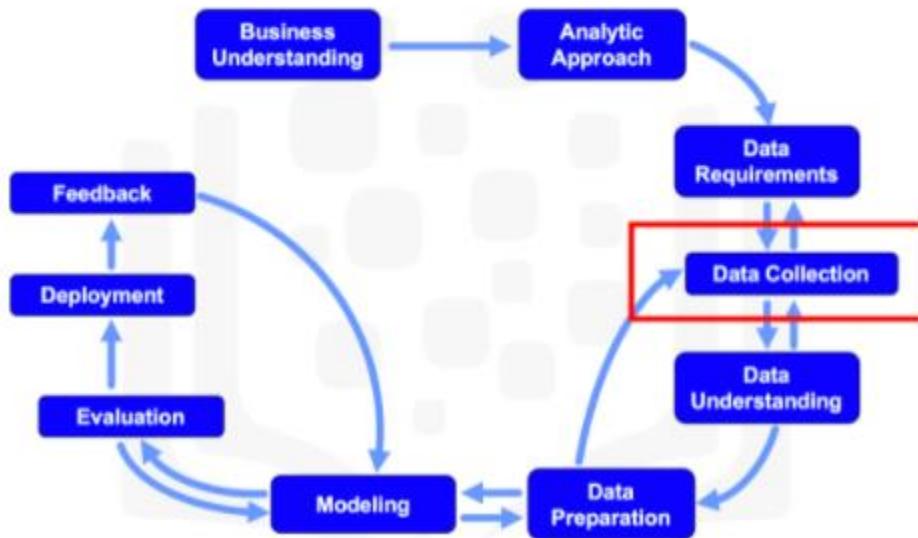

In the videos, we learned that the chosen analytic approach determines the data requirements. Specifically, the analytic methods to be used require certain data content, formats and representations, guided by domain knowledge.

In the **From Problem to Approach Lab**, we determined that automating the process of determining the cuisine of a given recipe or dish is potentially possible using the ingredients of the recipe or the dish. In order to build a model, we need extensive data of different cuisines and recipes.

Identifying the required data fulfills the data requirements stage of the data science methodology.

## Data Collection

In the initial data collection stage, data scientists identify and gather the available data resources. These can be in the form of structured, unstructured, and even semi-structured data relevant to problem domain.

### Web Scraping of Online Food Recipes

A researcher named Yong-Yeol Ahn scraped tens of thousands of food recipes (cuisines and ingredients) from three different websites, namely:

For more information on Yong-Yeol Ahn and his research, you can read his paper on Flavor Network and the Principles of Food Pairing.

In fact we will not need to carry out any data collection as the data that we need to meet the goal defined in the business understanding stage is readily available.

## Using this notebook:

To run any of the following cells of code, you can type **Shift + Enter** to execute the code in a cell.

Get the version of Python installed.

```
[ ]: # check Python version  
!python -V  
***
```

Read the data from the IBM server into a pandas dataframe.

```
[ ]: import pandas as pd # download library to read data into dataframe  
pd.set_option('display.max_columns', None)  
  
recipes = pd.read_csv("https://cf-courses-data.s3.us.cloud-object-storage.appdomain.cloud/IBMDeveloperSkillsNetwork-DS0103EN-SkillsNetwork/labs/Module%202/recipes.csv")  
print("Data read into dataframe!") # takes about 30 seconds  
***
```

\*\*\*

Show the first few rows.

```
[ ]: recipes.head()
```

\*\*\*

Get the dimensions of the dataframe.

```
[ ]: recipes.shape
```

\*\*\*

So our dataset consists of 57,691 recipes. Each row represents a recipe, and for each recipe, the corresponding cuisine is documented as well as whether 384 ingredients exist in the recipe or not beginning with almond and ending with zucchini.

---

Now that the data collection stage is complete, data scientists typically use descriptive statistics and visualization techniques to better understand the data and get acquainted with it. Data scientists, essentially, explore the data to:

- understand its content,
- assess its quality,
- discover any interesting preliminary insights and,
- determine whether additional data is necessary to fill any gaps in the data.

## Thank you for completing this lab!

This notebook is part of a course called *The Data Science Method*. If you accessed this notebook outside the course, you can take this course, online by clicking [here](#).

## Module Summary

 Bookmarked

In this module, you have learned:

- The significance of defining the data requirements for your model.
- Why the content, format, and representation of your data matter.
- The importance of identifying the correct sources of data for your project.
- How to handle unavailable and redundant data.
- To anticipate the needs of future stages in the process.

## Graded Review Questions

 Bookmarked

Quiz due Dec 10, 2021 05:34 CST Completed

### Instructions for Review Questions

#### 1. Time allowed: **Unlimited**

- We encourage you to go back and review the materials to find the right answer
- Please remember that the Review Questions are worth 60% of your final mark.

#### 2. Attempts per question:

- One attempt - For True/False questions
- Two attempts - For any question other than True/False

#### 3. Clicking the "**Final Check**" button when it appears, means your submission is **FINAL**. You will **NOT** be able to resubmit your answer for that question ever again

#### 4. Check your grades in the course at any time by clicking on the "Progress" tab

## Module 3 From Understanding to Preparation

### Learning Objectives

Bookmarked

### Learning Objectives

In this module you will:

- Learn what it means to understand data.
- Learn what it means to prepare or clean data.
- Learn about ways in which data is prepared.
- Learn how to complete the Data Understanding and the Data Preparation stages pertaining to any data science problem.

## Data Understanding

Data understanding encompasses all activities related to constructing the data set.

Essentially, the data understanding section of the data science methodology answers the question: Is the data that you collected representative of the problem to be solved?

Let's apply the data understanding stage of our methodology, to the case study we've

been examining.

In order to understand the data related to congestive heart failure admissions, descriptive statistics needed to be run against the data columns that would become variables in the model.

First, these statistics included Hearst, univariates, and statistics on each variable, such as mean, median, minimum, maximum, and standard deviation.

Second, pairwise correlations were used, to see how closely certain variables were related, and which ones, if any, were very highly correlated, meaning that they would be essentially redundant,

thus making only one relevant for modeling.

Third, histograms of the variables were examined to understand their distributions.

Histograms are a good way to understand how values or a variable are distributed, and which sorts of data preparation may be needed to make the variable more useful in a model.

For example, for a categorical variable that has too many distinct values to be informative in a model, the histogram would help them decide how to consolidate those values.

The univariates, statistics, and histograms are also used to assess data quality.

From the information provided, certain values can be re-coded or perhaps even dropped if necessary, such as when a certain variable has many missing values.

The question then becomes, does "missing" mean anything?

Sometimes a missing value might mean "no", or "0" (zero), or at other times it simply means "we don't know". Or, if a variable contains invalid or misleading values, such as a numeric variable called "age" that contains 0 to 100 and also 999, where that "triple-9" actually means "missing", but would be treated as a valid value unless we corrected it.

Initially, the meaning of congestive heart failure admission was decided on the basis of a primary diagnosis of congestive heart failure.

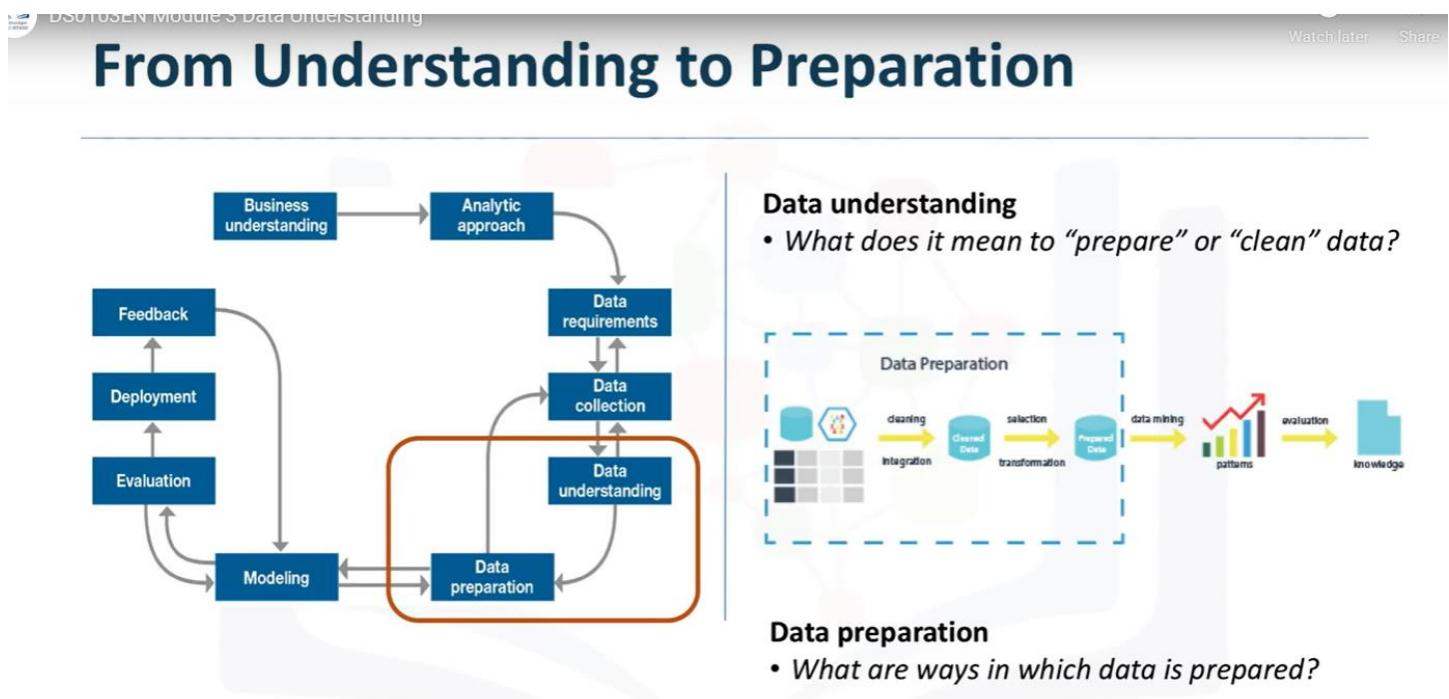

But working through the data understanding stage revealed that the initial definition was not capturing all of the congestive heart failure admissions that were expected, based on clinical experience.

This meant looping back to the data collection stage and adding secondary and tertiary diagnoses,

and building a more comprehensive definition of congestive heart failure admission.

This is just one example of the interactive processes in the methodology.

The more one works with the problem and the data, the more one learns and therefore the more refinement that can be done within the model, ultimately leading to a better solution to the problem.

# Case Study – Understanding the data

- Descriptive statistics
  - Univariate statistics
  - Pairwise correlations
  - Histogram

$$f(a) + \sum_{k=1}^n \frac{1}{k!} \frac{d^k}{dt^k} \Big|_{t=0} f(u(t)) + \int_0^1 \frac{(1-t)^n}{n!} \frac{d^{n+1}}{dt^{n+1}} f(u(t)) dt.$$

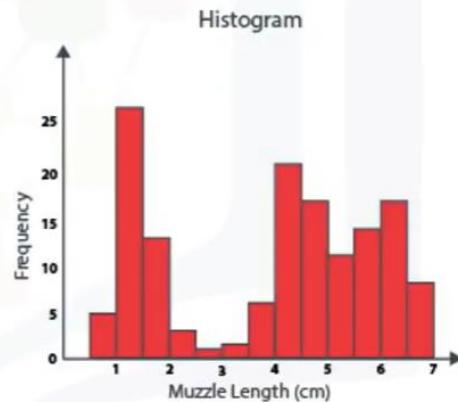

$F_{X,Y}(x,y)$  satisfies

$$F_{X,Y}(x,y) = F_X(x)F_Y(y),$$

or equivalently, their joint density  $f_{X,Y}(x,y)$  satisfies

$$f_{X,Y}(x,y) = f_X(x)f_Y(y).$$

Histograms are a good way to understand how values or a variable are distributed, and what sorts of data preparation may be needed to make the variable more useful in a model.

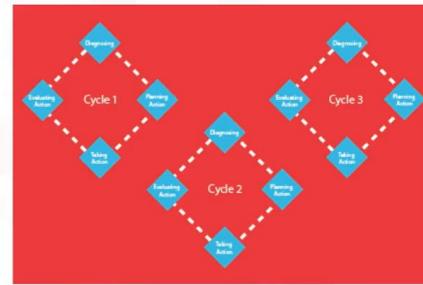

## Case study – Looking at data quality

- Data quality
  - Missing values
  - Invalid or misleading values

## Case study – This is an iterative process

- Iterative data collection and understanding
  - Refined definition of “CHF admission”

## Data Preparation – Cleansing the Data

In a sense, data preparation is similar to washing freshly picked vegetables in so far as unwanted elements, such as dirt or imperfections, are removed.

Together with data collection and data understanding, data preparation is the most time-consuming phase of a data science project, typically taking seventy percent and even up to even ninety percent of the overall project time.

Automating some of the data collection and preparation processes in the database, can reduce this time to as little as 50 percent.

This time savings translates into increased time for data scientists to focus on creating models.

To continue with our cooking metaphor, we know that the process of chopping onions to a finer state will allow for its flavours to spread through a sauce more easily than that would be the case if we were to drop the whole onion into the sauce pot.

Similarly, transforming data in the data preparation phase is the process of getting the data into a state where it may be easier to work with.

Specifically, the data preparation stage of the methodology answers the question: What are the ways in which data is prepared?

To work effectively with the data,

- it must be prepared in a way that addresses missing or invalid values and removes duplicates, toward ensuring that everything is properly formatted.
- Feature engineering is also part of data preparation. It is the process of using domain knowledge of the data to create features that make the machine learning algorithms work.
  - A feature is a characteristic that might help when solving a problem. Features within the data are important to predictive models and will influence the results you want to achieve.
  - Feature engineering is critical when machine learning tools are being applied to analyze the data.

When working with text, text analysis steps for coding the data are required to be able to manipulate the data.

The data scientist needs to know what they're looking for within their dataset to address the question.

- The text analysis is critical to ensure that the proper groupings are set, and that the programming is not overlooking what is hidden within.

The data preparation phase sets the stage for the next steps in addressing the question.

While this phase may take a while to do, if done right the results will support the project.

If this is skipped over, then the outcome will not be up to par and may have you back at the drawing board.

It is vital to take your time in this area, and use the tools available to automate common steps to accelerate data preparation.

Make sure to pay attention to the detail in this area.

After all, it takes just one bad ingredient to ruin a fine meal.

Feature engineering is critical when machine learning tools are being applied to analyze the data.

# Working with text analysis

## Data Preparation - Case Study

In a sense, data preparation is similar to washing freshly picked vegetables insofar as unwanted elements, such as dirt or imperfections, are removed.

So now, let's look at the case study related to applying Data Preparation concepts.

In the case study, an important first step in the data preparation stage was to actually define congestive heart failure.

This sounded easy at first but defining it precisely, was not straightforward.

First, the set of diagnosis-related group codes needed to be identified, as congestive heart failure implies certain kinds of fluid buildup.

We also needed to consider that congestive heart failure is only one type of heart failure.

Clinical guidance was needed to get the right codes for congestive heart failure.

The next step involved defining the re-admission criteria for the same condition.

The timing of events needed to be evaluated in order to define whether a particular congestive heart failure admission was an initial event, which is called an index admission, or a congestive heart failure-related re-admission.

Based on clinical expertise, a time period of 30 days was set as the window for readmission relevant for congestive heart failure patients, following the discharge from the initial admission.

Next, the records that were in transactional format were aggregated, meaning that the data included multiple records for each patient.

Transactional records included professional provider facility claims submitted for physician, laboratory, hospital, and clinical services.

Also included were records describing all the diagnoses, procedures, prescriptions, and other information about in-patients and out-patients.

A given patient could easily have hundreds or even thousands of these records, depending on their clinical history.

Then, all the transactional records were aggregated to the patient level, yielding a single record for each patient, as required for the decision-tree classification method that would be used for modeling.

As part of the aggregation process, many new columns were created representing the information

in the transactions.

For example, frequency and most recent visits to doctors, clinics and hospitals with diagnoses, procedures, prescriptions, and so forth.

Co-morbidities with congestive heart failure were also considered, such as diabetes, hypertension, and many other diseases and chronic conditions that could impact the risk of re-admission for congestive heart failure.

During discussions around data preparation, a literary review on congestive heart failure was also undertaken to see whether any important data elements were overlooked, such as co-morbidities that had not yet been accounted for.

- The literary review involved looping back to the data collection stage to add a few more indicators for conditions and procedures.
- Aggregating the transactional data at the patient level, meant merging it with the other patient data, including their demographic information, such as age, gender, type of insurance, and so forth.

The result was the creation of one table containing a single record per patient, with many columns representing the attributes about the patient in his or her clinical history. These columns would be used as variables in the predictive modeling.

Here is a list of the variables that were ultimately used in building the model.

The dependent variable, or target, was congestive heart failure readmission within 30 days following discharge from a hospitalization for congestive heart failure, with an outcome of either yes or no.

The data preparation stage resulted in a cohort of 2,343 patients meeting all of the criteria for this case study. The cohort was then split into training and testing sets for building and validating the model, respectively.

This ends the Data Preparation section of this course, in which we applied the key concepts to the case study.

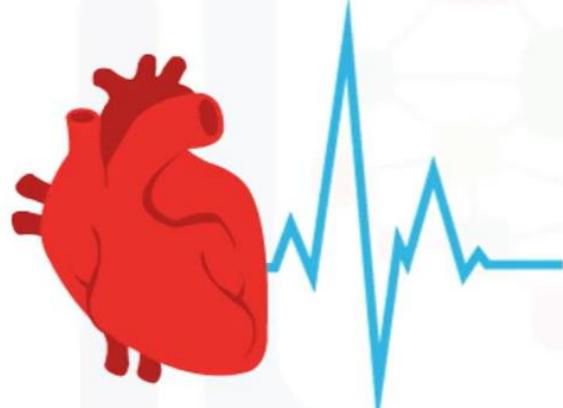

# Data Science Methodology

# Data preparation – Cleansing data

## Case Study – Applying the concepts

### Case Study – Data preparation

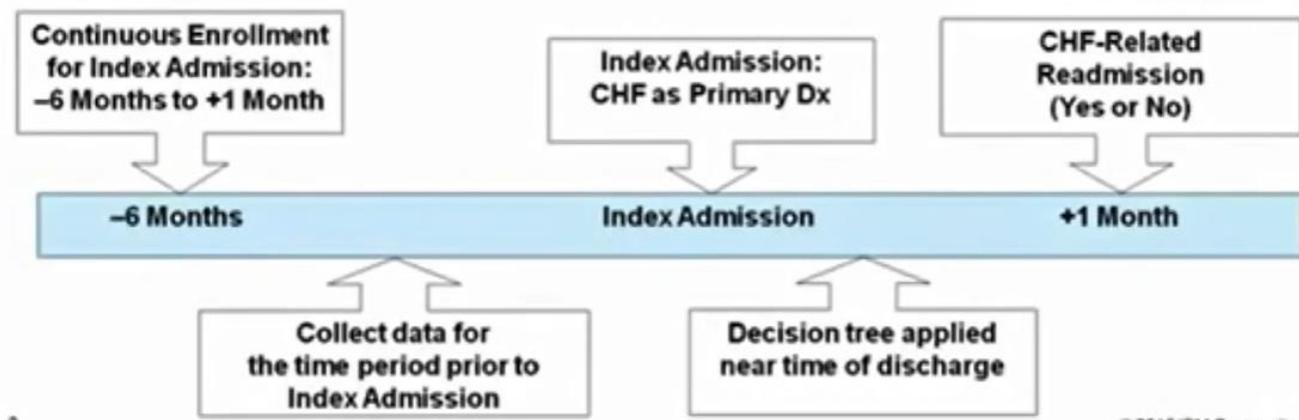

### Case Study – Defining readmission

# Case Study – Defining CHF admission

Define “CFF admission” and “CHF readmission”

© 2015 IBM Corporation

## Case Study – Aggregating records

Transactional records

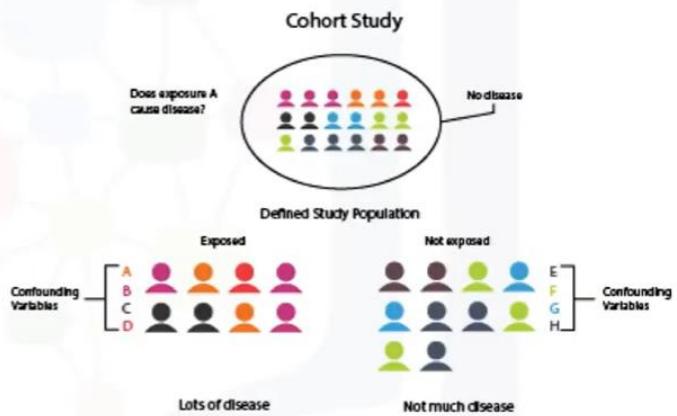

- Claims: professional provider, facility, pharmaceutical
- Inpatient & outpatient records: diagnoses, procedures, prescriptions, etc.
- Possibly thousands per patient, depending on clinical history

# Case Study – Aggregating to patient level

Aggregate to patient level

- Roll up to 1 record per patient
- Create new columns representing the transaction
  - Outpatients visits/
  - Inpatient episodes: frequency, recency, diagnoses/length of stay, procedures, prescriptions
  - Comorbidities with CHF

# Case Study – More or less data needed?

Literature review of important factors for CHF readmission

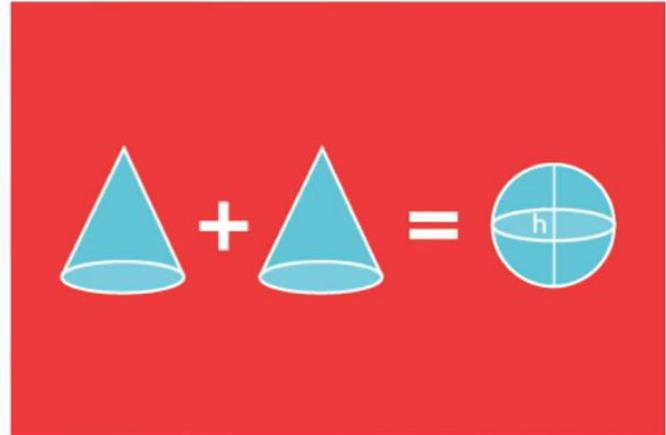

## MORE LIKELY TO BE READMITTED

- Medicare / Medicaid insurance holders
- Comorbid conditions including:
  - Ischemic heart disease
  - Idiopathic Cardiomyopathy
  - Prior Cardiac surgery
  - Peripheral vascular disease
  - Diabetes mellitus
  - Anemia

## LESS LIKELY TO BE READMITTED

- Patients treated at rural hospitals
- Patients discharged to skilled nursing facilities
- Patients receiving echocardiograms or cardiac catheterization

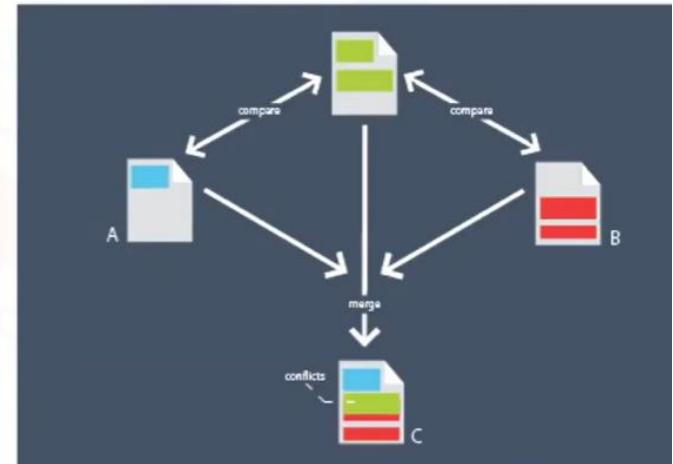

- Loop back to data collection stage and add additional data, if needed

# Case Study – Completing the data set

Merge all data into one table

- One record per patient
- List of variables used in modeling
  - Target: CHF readmission with 30 days (Yes/No), following discharge from CHF hospitalization

# Case Study – Creating new variables

Merge all data into one table

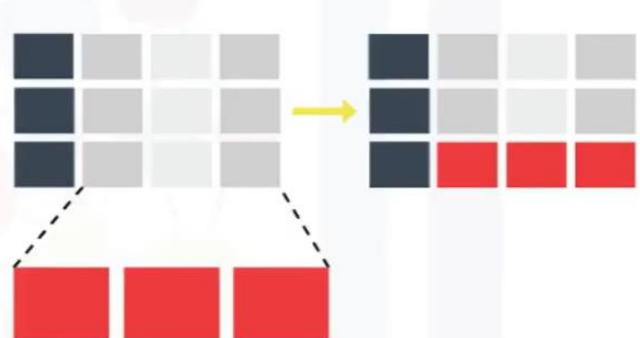

- One record per patient
- List of variables used in modeling

– Target

CHF readmission with 30 days (Yes/No), following discharge from CHF hospitalization

– Measures

Gender	Length of stay	CHF Diagnosis importance (primary, secondary, tertiary)
Age	Prior admissions	
Primary DRG	Line of business	
– Diagnosis flags (Y/N)		
CHF	Atrial fibrillation	Pneumonia
Diabetes	Renal failure	Hypertension

## Case Study – Using training sets

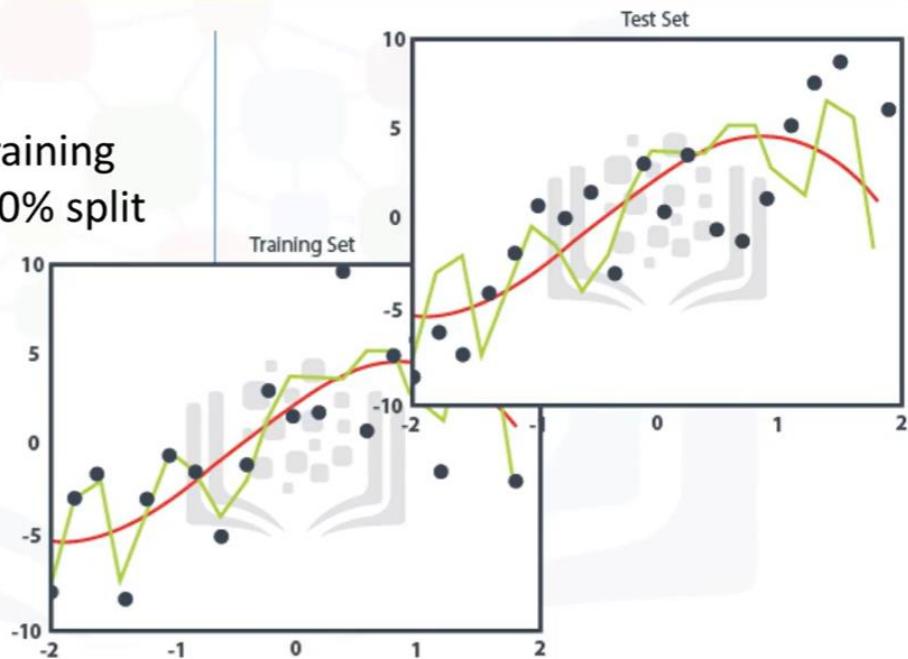

Cohort: 2,343 patients

Randomly divided into training and testing sets: 70% / 30% split

Training: 1,640 patients

Testing: 703 patients

## Graded Review Questions

 Bookmarked

### Question 1

1/1 point (graded)

Select the correct statement about the Data Understanding stage.

- The Data Understanding stage encompasses sorting the data.
- The Data Understanding stage encompasses all activities related to constructing the dataset.
- The Data Understanding stage encompasses removing redundant data.
- All of the above statements about the Data Understanding stage are correct.

### Answer

Correct: Correct

## Question 2

0/1 point (graded)

In the case study, working through the Data Preparation stage, it was revealed that the initial definition was not capturing all of the congestive heart failure admissions that were expected, based on clinical experience.

True

False

✗

### Answer

Incorrect:

Incorrect, It was working through the Data Understanding staging that the initial definition was found to be incomplete

## Question 3

1/1 point (graded)

Select the correct statement about the Data Preparation stage.

The Data Preparation stage involves addressing missing values.

The Data Preparation stage involves correcting invalid values and addressing outliers.

The Data Preparation stage involves removing duplicate data.

The Data Preparation stage involves properly formatting the data.

All of the above statements are correct.

✓

**Submit**

## Learning Objectives

Bookmark this page

### Learning Objectives

In this module you will:

- Learn what the purpose of data modeling is.
- Learn about some characteristics of the modeling process.
- Learn about what it means to evaluate a model and ways in which a model is evaluated.
- Learn how to complete the Modeling and the Model Evaluation stages pertaining to any data science problem.

# FROM MODELING TO EVALUATION

## Module 4 - Modelling Concepts

Modelling is the stage in the data science methodology where the data scientist has the chance to sample the sauce and determine if it's bang on or in need of more seasoning!

This portion of the course is geared toward answering two key questions:

- First, what is the purpose of data modeling, and
- second, what are some characteristics of this process?

Data Modelling focuses on developing models that are either descriptive or predictive.

- An example of a descriptive model might examine things like: if a person did this, then they're likely to prefer that.

A predictive model tries to yield yes/no, or stop/go type outcomes.

These models are based on the analytic approach that was taken, either statistically driven or machine learning driven.

The data scientist will use a training set for predictive modelling.

- A training set is a set of historical data in which the outcomes are already known.
- The training set acts like a gauge to determine if the model needs to be calibrated.
- In this stage, the data scientist will play around with different algorithms to ensure that the variables in play are actually required.

The success of data compilation, preparation and modelling, depends on the understanding

of the problem at hand, and the appropriate analytical approach being taken.

The data supports the answering of the question, and like the quality of the ingredients in cooking, sets the stage for the outcome.

Constant refinement, adjustments and tweaking are necessary within each step to ensure the outcome is one that is solid.

In John Rollins' descriptive Data Science Methodology, the framework is geared to do 3 things:

- First, understand the question at hand.
- Second, select an analytic approach or method to solve the problem, and
- Third, obtain, understand, prepare, and model the data.
- The end goal is to move the data scientist to a point where a data model can be built to answer the question. With dinner just about to be served and a hungry guest at the table, the key question is: Have I made enough to eat?

Well, let's hope so.

In this stage of the methodology, model evaluation, deployment, and feedback loops ensure that the answer is near and relevant.

This relevance is critical to the data science field

overall, as it is a fairly new field of study, and we are interested in the possibilities it has to offer.

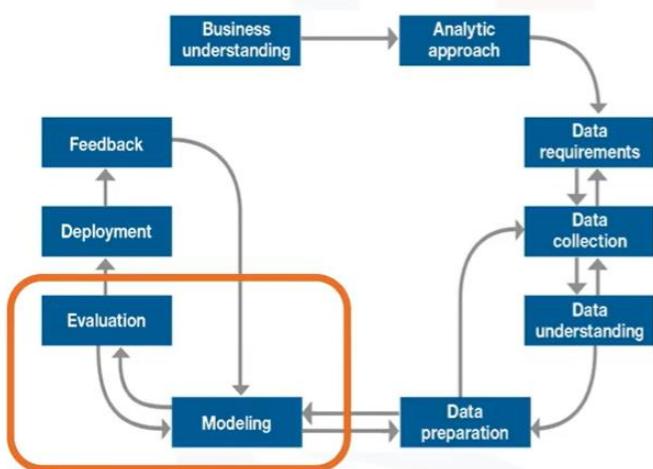

The more people that benefit from the outcomes of this practice, the further the field will develop.

This ends the Modeling to Evaluation section of this course, in which we reviewed the key concepts related to modeling. Thanks for watching!

## Modeling Case Study

Modelling is the stage in the data science methodology where the data scientist has the chance to sample the sauce and determine if it's bang on or in need of more seasoning!

Now, let's apply the case study to the modeling stage within the data science methodology.

Here, we'll discuss one of the many aspects of model building, in this case, parameter tuning to improve the model.

With a prepared training set, the first decision tree classification model for congestive heart failure readmission can be built.

We are looking for patients with high-risk readmission, so the outcome of interest will be congestive heart failure readmission equals "yes".

In this first model, overall accuracy in classifying the yes and no outcomes was 85%.

This sounds good, but it represents only 45% of the "yes". The actual readmissions are correctly classified, meaning that the model is not very accurate.

The question then becomes: How could the accuracy of the model be improved in predicting the yes outcome?

For decision tree classification, the best parameter to adjust is the relative cost of misclassified yes and no outcomes.

Think of it like this:

When a true, non-readmission is misclassified, and action is taken to reduce that patient's risk, the cost of that error is the wasted intervention.

A statistician calls this a type I error, or a false-positive.

But when a true readmission is misclassified, and no action is taken to reduce that risk, then the cost of that error is the readmission and all its attended costs, plus the trauma to the patient.

This is a type II error, or a false-negative.

So we can see that the costs of the two different kinds of misclassification errors can be quite different.

For this reason, it's reasonable to adjust the relative weights of misclassifying the yes and no outcomes.

The default is 1-to-1, but the decision tree algorithm, allows the setting of a higher

value for yes.

For the second model, the relative cost was set at 9-to-1.

This is a very high ratio, but gives more insight to the model's behaviour.

This time the model correctly classified 97% of the yes, but at the expense of a very low accuracy on the no, with an overall accuracy of only 49%.

This was clearly not a good model.

The problem with this outcome is the large number of false-positives, which would recommend unnecessary and costly intervention for patients, who would not have been re-admitted anyway.

Therefore, the data scientist needs to try again to find a better balance between the yes and no accuracies.

For the third model, the relative cost was set at a more reasonable 4-to-1.

This time 68% accuracy was obtained on only yes, called sensitivity by statisticians, and 85% accuracy on the no, called specificity, with an overall accuracy of 81%.

This is the best balance that can be obtained with a rather small training set through adjusting the relative cost of misclassified yes and no outcomes parameter.

A lot more work goes into the modeling, of course, including iterating back to the data preparation stage to redefine some of the other variables, so as to better represent the underlying information, and thereby improve the model.

## Modeling – Sampling the food (the data)...

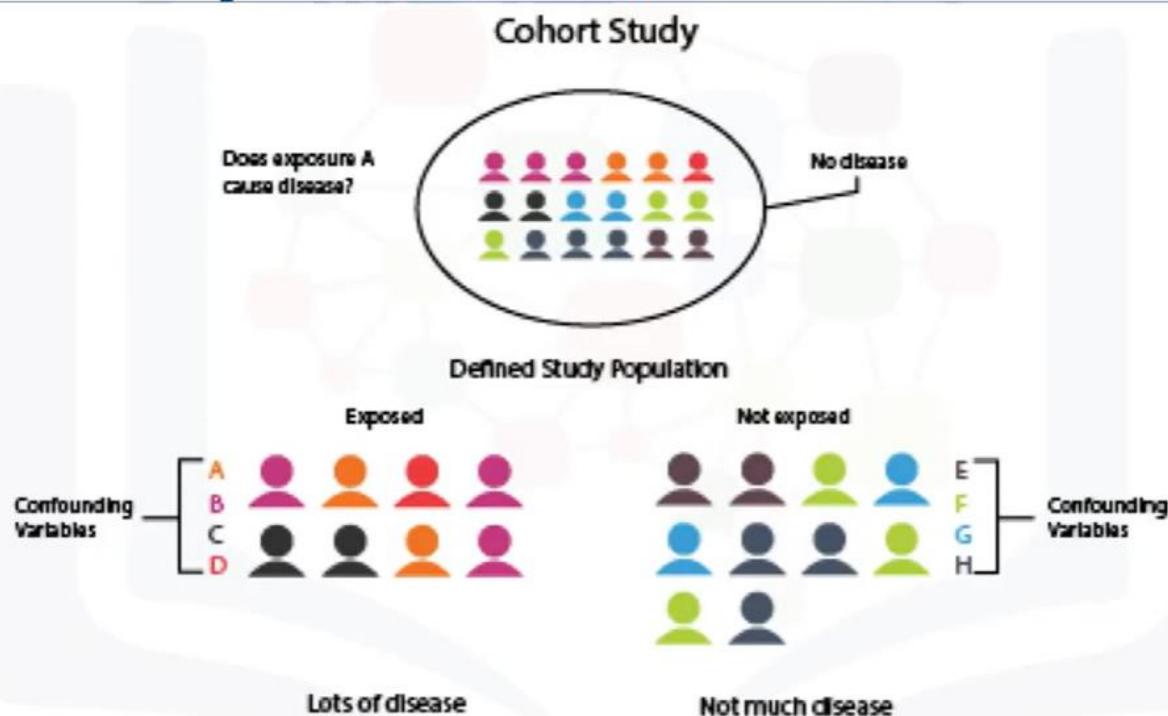

## Case Study – Analyzing the 1<sup>st</sup> model

Initial decision tree classification model

- Low accuracy on “Yes” outcome

Model	Relative Cost Y:N	Overall Accuracy (% correct Y & N)	Sensitivity (Y accuracy)	Specificity (N accuracy)
→ 1	1:1	85%	45%	97%
2	9:1	49%	97%	35%
3	4:1	81%	68%	85%

## Case Study – How to improve the model?

## Case Study – Analyzing the 2<sup>nd</sup> model

Second model

- High accuracy on “Yes” but poor on “No”

Model	Relative Cost Y:N	Overall Accuracy (% correct Y & N)	Sensitivity (Y accuracy)	Specificity (N accuracy)
→ 1	1:1	85%	45%	97%
→ 2	9:1	49%	97%	35%
3	4:1	81%	68%	85%

## Case Study – Analyzing the 3<sup>rd</sup> model

Third model

- Better balance on “Yes” and “No” accuracy

Model	Relative Cost Y:N	Overall Accuracy (% correct Y & N)	Sensitivity (Y accuracy)	Specificity (N accuracy)
→ 1	1:1	85%	45%	97%
→ 2	9:1	49%	97%	35%
→ 3	4:1	81%	68%	85%

## From Modelling to Evaluation

A model evaluation goes hand-in-hand with model building as such, the modeling and evaluation stages are done iteratively.

- Model evaluation is performed during model development and before the model is deployed.
- Evaluation allows the quality of the model to be assessed but it's also an opportunity to see if it meets the initial request.
- Evaluation answers the question: Does the model used really answer the initial question or does it need to be adjusted?

Model evaluation can have two main phases.

- The first is the diagnostic measures phase, which is used to ensure the model is working as intended. If the model is a predictive model, a decision tree can be used to evaluate if the answer the model can output, is aligned to the initial design.
  - It can be used to see where there are areas that require adjustments.
- If the model is a descriptive model, one in which relationships are being assessed, then a testing set with known outcomes can be applied, and the model can be refined as needed.
- The second phase of evaluation that may be used is statistical significance testing.

This type of evaluation can be applied to the model to ensure that the data is being properly handled and interpreted within the model. This is designed to avoid unnecessary second guessing when the answer is revealed.

So now, let's go back to our case study so that we can apply the "Evaluation" component within the data science methodology.

Let's look at one way to find the optimal model through a diagnostic measure based on tuning one of the parameters in model building.

Specifically we'll see how to tune the relative cost of misclassifying yes and no outcomes. As shown in this table, four models were built with four different relative misclassification costs.

As we see, each value of this model-building parameter increases the true-positive rate, or sensitivity, of the accuracy in predicting yes, at the expense of lower accuracy in predicting no, that is, an increasing false-positive rate.

The question then becomes, which model is best based on tuning this parameter?

For budgetary reasons, the risk-reducing intervention could not be applied to most or all congestive heart failure patients, many of whom would not have been readmitted anyway.

On the other hand, the intervention would not be as effective in improving patient care as it should be, with not enough high-risk congestive heart failure patients targeted. So, how do we determine which model was optimal?

As you can see on this slide, the optimal model is the one giving the maximum separation between the blue ROC curve relative to the red base line.

We can see that model 3, with a relative misclassification cost of 4-to-1, is the best of the 4 models.

And just in case you were wondering, ROC stands for receiver operating characteristic curve, which was first developed during World War II to detect enemy aircraft on radar.

It has since been used in many other fields as well.

- Today it is commonly used in machine learning and data mining.
- The ROC curve is a useful diagnostic tool in determining the optimal classification model. This curve quantifies how well a binary classification model performs, declassifying the yes and no outcomes when some discrimination criterion is varied.

In this case, the criterion is a relative misclassification cost.

By plotting the true-positive rate against the false-positive rate for different values of the relative misclassification cost, the ROC curve helped in selecting the optimal model.

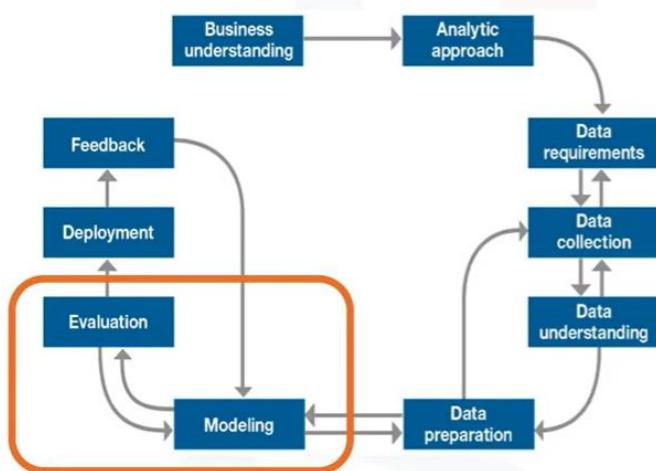

# Data Science Methodology

## Case Study – Applying the concepts

## Case Study – How to determine the optimal model?

Misclassification cost tuning

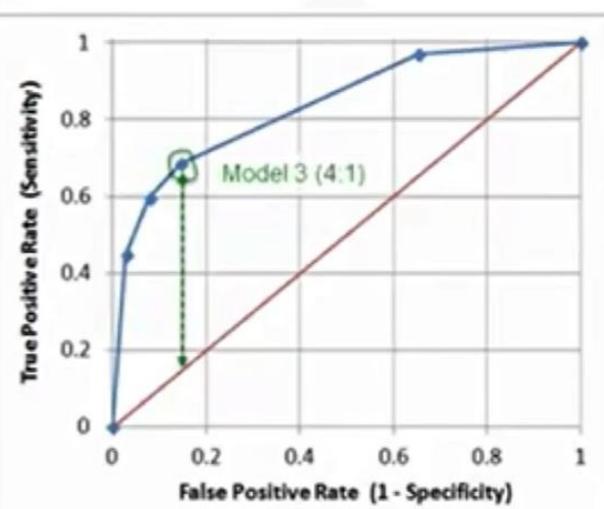

- Tune the relative misclassification costs
- Balance true-positive rate and false-positive rate for best model

Model	Relative Cost Y:N	True Positive Rate (Sensitivity)	Specificity (accuracy on N)	False Positive Rate (1 – Specificity)
1	1:1	0.45	0.97	0.03
2	1.5:1	0.60	0.92	0.08
3	4:1	0.68	0.85	0.15
4	9:1	0.97	0.35	0.65

## Cost Study – Using the ROC curve

Diagnostic tool for classification model evaluation

- Classification model performance
- True-Positive Rate vs False-Positive Rate
- Optimal model at maximum separation

## Learning Objectives

## Learning Objectives

In this module you will:

- Learn about what happens when a model is deployed.
- Learn about why model feedback is important.

## Module 5 – From Deployment to Feedback

While a data science model will provide an answer, the key to making the answer relevant and useful to address the initial question, involves getting the stakeholders familiar with the tool produced.

In a business scenario, stakeholders have different specialties that will help make this happen, such as the solution owner, marketing, application developers, and IT administration. Once the model is evaluated and the data scientist is confident it will work, it is deployed and put to the ultimate test.

1. Depending on the purpose of the model, it may be rolled out to a limited group of users or in a test environment, to build up confidence in applying the outcome for use across the board.

So now, let's look at the case study related to applying Deployment"

In preparation for solution deployment,

2. the next step was to assimilate the knowledge for the business group who would be designing and managing the intervention program to reduce readmission risk.
3. In this scenario, the business people translated the model results so that the clinical staff could understand how to identify high-risk patients and design suitable intervention actions. The goal, of course, was to reduce the likelihood that these patients would be readmitted within 30 days after discharge.
4. During the business requirements stage, the Intervention Program Director and her team had wanted an application that would provide automated, near real-time risk assessments of congestive heart failure.

5. It also had to be easy for clinical staff to use, and preferably through browser-based application on a tablet, that each staff member could carry around.
6. This patient data was generated throughout the hospital stay. It would be automatically prepared in a format needed by the model and each patient would be scored near the time of discharge.
7. Clinicians would then have the most up-to-date risk assessment for each patient, helping them to select which patients to target for intervention after discharge. As part of solution deployment, the Intervention team would develop and deliver training for the clinical staff.
8. Also, processes for tracking and monitoring patients receiving the intervention would have to be developed in collaboration with IT developers and database administrators, so that the results could go through the feedback stage and the model could be refined overtime.

This map is an example of a solution deployed through a Cognos application.

In this case, the case study was hospitalization risk for patients with juvenile diabetes.

Like the congestive heart failure use case, this one used decision tree classification to create a risk model that would serve as the foundation for this application.

The map gives an overview of hospitalization risk nationwide, with an interactive analysis of predicted risk by a variety of patient conditions and other characteristics.

This slide shows an interactive summary report of risk by patient population within a given node of the model, so that clinicians could understand the combination of conditions for this subgroup of patients. And this report gives a detailed summary on an individual patient, including the patient's

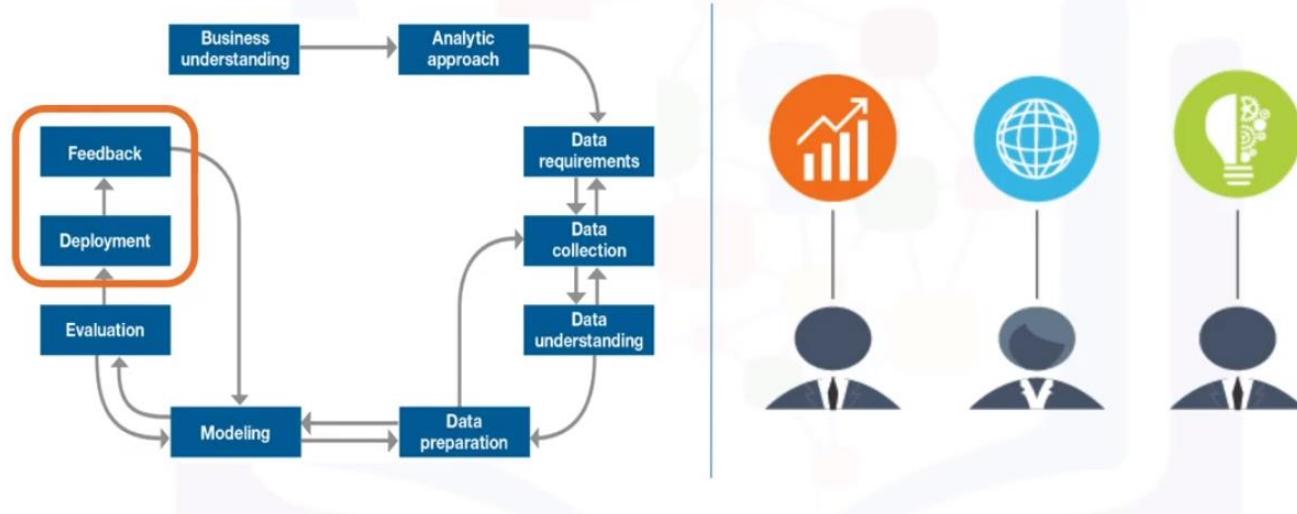

predicted risk and details about the clinical history, giving a concise summary for the doctor.

## Feedback

Once in play, feedback

- from the users will help to refine the model and assess it for performance and impact.
- The value of the model will be dependent on successfully incorporating feedback and making adjustments for as long as the solution is required.

Throughout the Data Science Methodology, each step sets the stage for the next.

- Making the methodology cyclical, ensures refinement at each stage in the game.
- The feedback process is rooted in the notion that, the more you know, the more that you'll want to know. That's the way John Rollins sees it and hopefully you do too.

Once the model is evaluated and the data scientist is confident it'll work, it is deployed and put to the ultimate test: actual, real-time use in the field.

So now, let's look at our case study again, to see how the Feedback portion of the methodology is applied.

The plan for the feedback stage included these steps:

1. First, the review process would be defined and put into place, with overall responsibility for measuring the results of a "flying to risk" model of the congestive heart failure risk population. Clinical management executives would have overall responsibility for the review process.
2. Second, congestive heart failure patients receiving intervention would be tracked and their re-admission outcomes recorded.
3. Third, the intervention would then be measured to determine how effective it was in reducing re-admissions.

For ethical reasons, congestive heart failure patients would not be split into controlled and treatment groups.

Instead, readmission rates would be compared before and after the implementation of the model to measure its impact.

After the deployment and feedback stages, the impact of the intervention program on re-admission rates would be reviewed after the first year of its implementation.

Then the model would be refined, based on all of the data compiled after model implementation and the knowledge gained throughout these stages.

4. Other refinements included: Incorporating information about participation in the intervention program, and possibly refining the model to incorporate detailed pharmaceutical data.

If you recall, data collection was initially deferred because the pharmaceutical data was

not readily available at the time. But after feedback and practical experience with the model, it might be determined that adding that data could be worth the investment of effort and time.

We also have to allow for the possibility that other refinements might present themselves during the feedback stage. Also, the intervention actions and processes would be reviewed and very likely refined as well, based on the experience and knowledge gained through initial deployment and feedback.

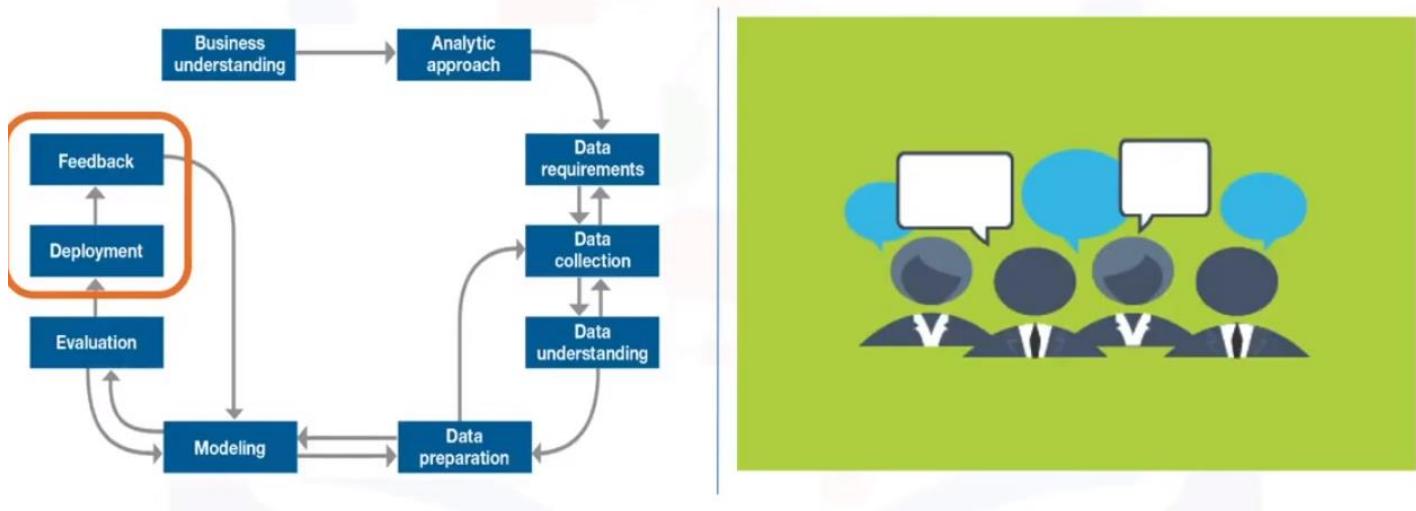

Finally, the refined model and intervention actions would be redeployed, with the feedback process continued throughout the life of the Intervention program.

# Data Science Methodology

## Feedback

### Feedback – Problem solved? Question answered?

### Feedback – Problem solved? Question answered?

## From Deployment to Feedback

Once the model is evaluated and the data scientist is confident it will work, it is deployed and put to the ultimate test

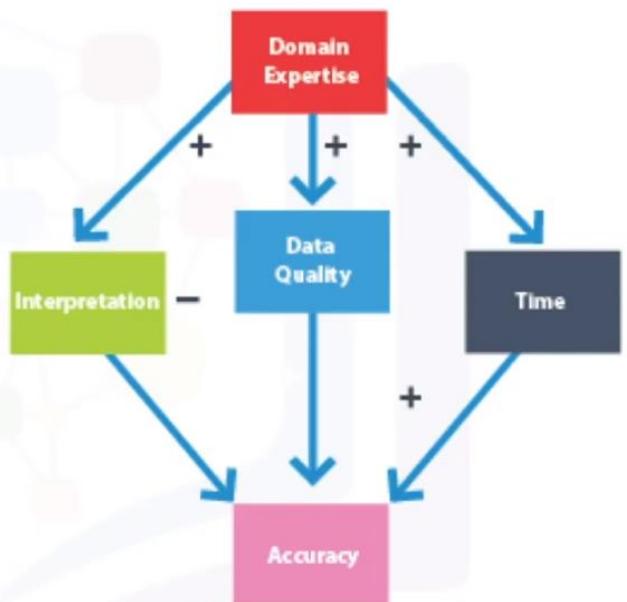

- Actual real-time use in the field

## Case Study – Applying the concepts

### Case Study – Assessing model performance

Define review process

- To measure results of applying the risk model to the CHF patient population
- Track patients who received intervention
  - Actual readmission outcomes
- Measure effectiveness of intervention
  - Compare readmission rates before & after model implementation

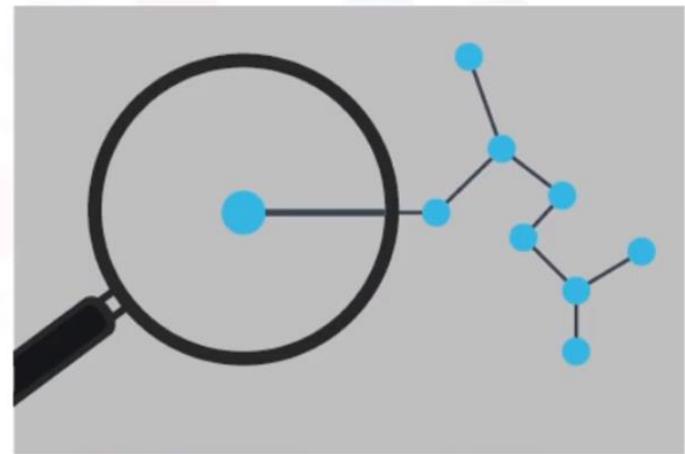

## Case Study – Refinement

Refine model

- Initial review after the first year of implementation
- Based on feedback data and knowledge gained
- Participation in intervention program
- Possibly incorporate detailed pharmaceutical data originally deferred
- Other possible refinements as yet unknown

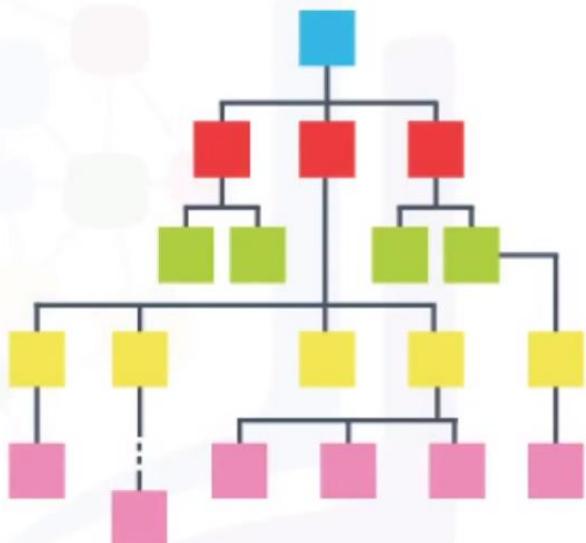

## Case Study – Redeployment

Review and refine intervention actions

Redeploy

- Continue modeling, deployment, feedback, and refinement throughout the life of the intervention program

## Module Summary

In this lesson, you have learned:

- The importance of stakeholder input.
- To consider the scale of deployment.
- The importance of incorporating feedback to refine the model.
- The refined model must be redeployed.
- This process should be repeated as often as necessary.

## Graded Review Questions

---

## Question 1

1 point possible (graded)

The final stages of the data science methodology are an iterative cycle between Modelling, Evaluation, Deployment, and Feedback.

True

False

**Submit**

You have used 0 of 1 attempt

**Save**

---

## Question 2

1 point possible (graded)

Select the correct statement about the Feedback stage of the data science methodology.

Feedback is not required once launched.

Feedback is not helpful and gets in the way.

Feedback is essential to the long term viability of the model.

None of the above statements are correct.

**Submit**

You have used 0 of 2 attempts

**Save**

---

## Question 3

1 point possible (graded)

Deploying a model into production represents the end of the iterative process that includes Feedback, Model Refinement, and Redeployment.

True.

False

**Submit**

You have used 0 of 1 attempt

**Save**

## Question 4

1 point possible (graded)

Select the correct sentence about the data science methodology explained in the course

- The data science methodology provides the data scientist with a framework on how to proceed to obtain answers.
- The data science methodology always starts with data collection.
- The data science methodology is not an iterative process – one does not go back and forth between methodological steps.
- The data science methodology depends on a specific set of technologies or tools.

Submit

You have used 0 of 2 attempts

Save

## Question 5

1 point possible (graded)

A data scientist determines that building a recommender system is the solution for a particular business problem at hand. What stage of the data science methodology does this represent?

- Modeling.
- Model Evaluation.
- Analytic Approach.
- Deployment.

Submit

You have used 0 of 2 attempts

Save

## Course Summary (3:30)

We've come to the end of our story, one that we hope you'll share.

You've learned how to think like a data scientist, including taking the steps involved in tackling a data science problem and applying them to interesting, real-world examples.

These steps have included:

- forming a concrete business or research problem, collecting and analyzing data, building a model, and understanding the feedback after model deployment.

In this course, you've also learned methodical ways of moving from problem to approach, including the importance of understanding the question, the business goals and objectives, and picking the most effective analytic approach to answer the question and solve the problem.

You've also learned methodical ways of working with the data, specifically, determining the data requirements, collecting the appropriate data, understanding the data, and then preparing the data for modeling!

You've also learned how to model the data by using the appropriate analytic approach, based on the data requirements and the problem that you were trying to solve. Once the approach was selected, you learned the steps involved in evaluating and deploying the model, getting feedback on it, and using that feedback constructively so as to improve the model.

Remember that the stages of this methodology are iterative!

This means that the model can always be improved for as long as the solution is needed, regardless of whether the improvements come from constructive feedback, or from examining newly available data sources.

Using a real case study,

- you learned how data science methodology can be applied in context, toward successfully achieving the goals that were set out in the business requirements stage.
- You also saw how the methodology contributed additional value to business units by incorporating data science practices into their daily analysis and reporting functions.
- The success of this new pilot program that was reviewed in the case study was evident by the fact that physicians were able to deliver better patient care by using new tools to incorporate timely data-driven information into patient care decisions.

And finally, you learned, in a nutshell, the true meaning of a methodology!

That its purpose is to explain how to look at a problem, work with data in support of solving the problem, and come up with an answer that addresses the root problem.

By answering 10 simple questions methodically, we've taught you that a methodology can

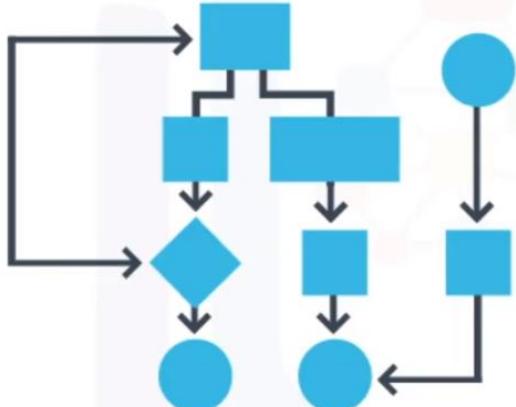

help you solve not only your data science problems, but also any other problem. Your success within the data science field depends on your ability to apply the right tools, at the right time, in the right order, to the address the right problem. And that is the way John Rollins sees it! We hope you've enjoyed taking the Data Science Methodology course and found it to be a valuable experience one that you'll share with others!

# Data Science Methodology

## Course Summary

### We've come to the end of the story

#### From problem to approach

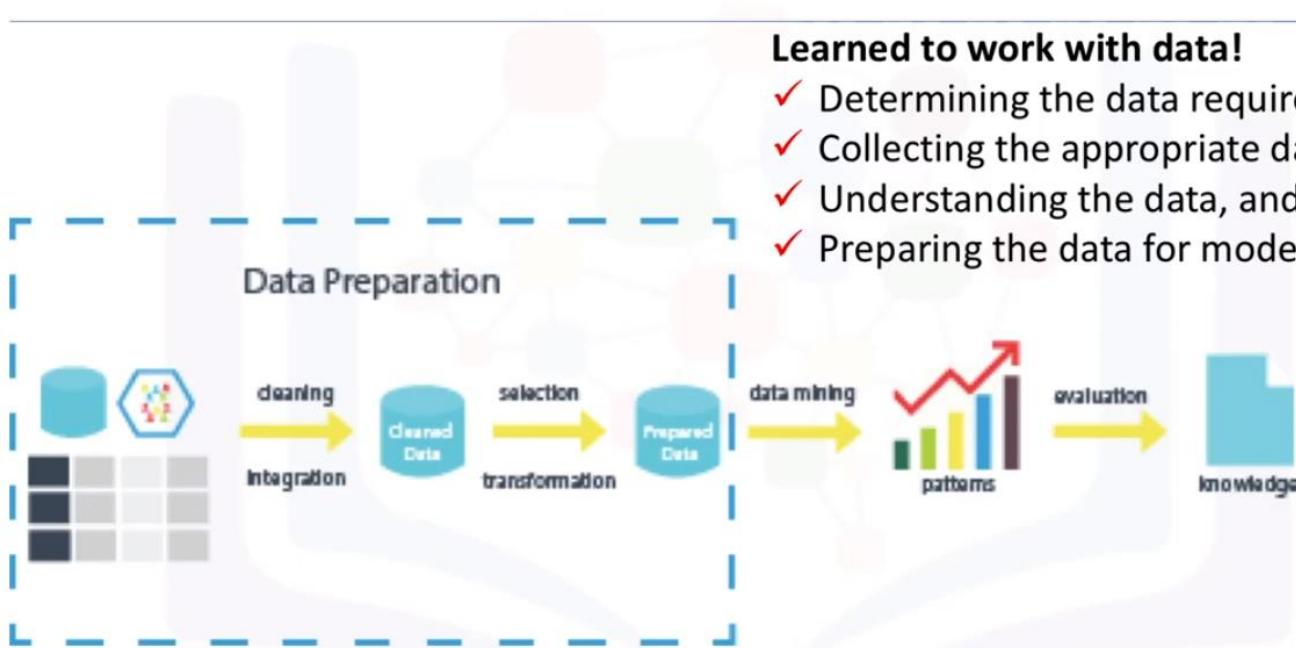

#### Thinking like a data scientist!

- ✓ Forming a concrete business or research problem,
- ✓ Collecting and analyzing data,
- ✓ Building a model, and
- ✓ Understanding the feedback after model deployment.

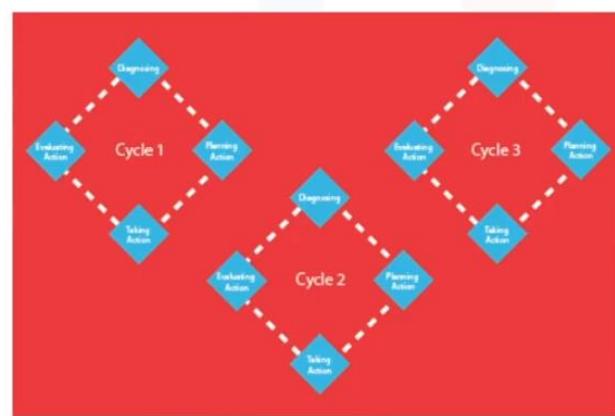

#### Learned importance of:

- ✓ Understanding the question, and
- ✓ Picking the most effective analytic approach

# To working with the data

# To deriving the answer

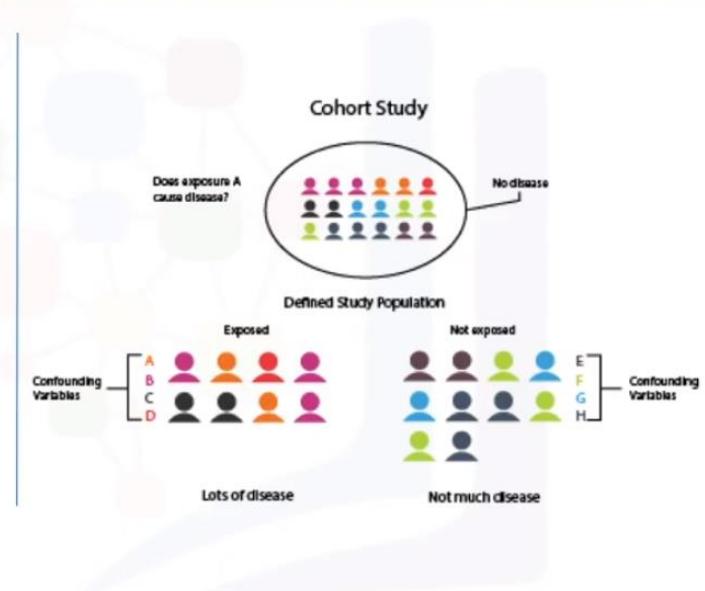

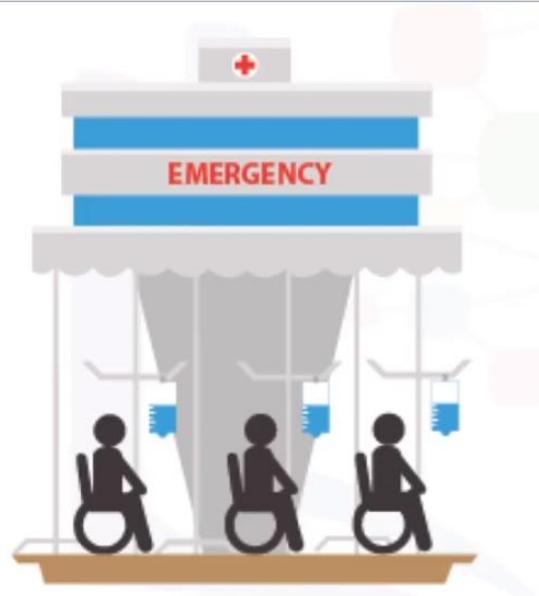

Once the analytic approach is selected, learned how to derive the answer:

- ✓ Evaluating and deploying the model,
- ✓ Getting feedback on it, and
- ✓ Using that feedback constructively so as to improve the model.

Remember that the stages of this methodology are **iterative**!

# Applied the concepts using a Case Study

DS0103EN Course Summary

## The methodology in a nutshell...

The **Data Science Methodology** aims to answer the following 10 questions in this prescribed sequence:

### From problem to approach:

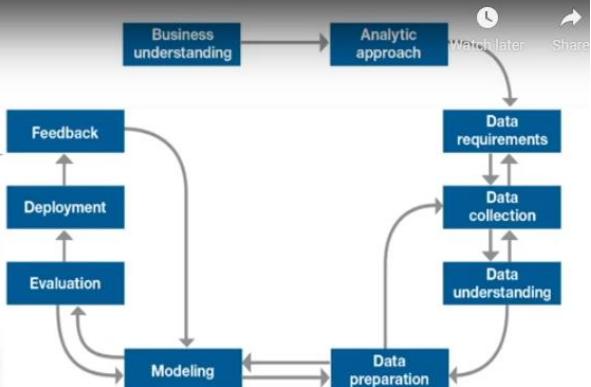

1. *What is the problem that you are trying to solve?*
2. *How can you use data to answer the question?*

### Working with the data:

3. *What data do you need to answer the question?*
4. *Where is the data coming from (identify all sources) and how will you get it?*
5. *Is the data that you collected representative of the problem to be solved?*
6. *What additional work is required to manipulate and work with the data?*

### Deriving the answer:

7. *In what way can the data be visualized to get to the answer that is required?*
8. *Does the model used really answer the initial question or does it need to be adjusted?*
9. *Can you put the model into practice?*
10. *Can you get constructive feedback into answering the question?*

# The process must fit the problem!

*And that is the way John Rollins sees it!*

**John Rollins**

Data Scientist, IBM Analytics, IBM

What are the pieces  
of your puzzle?
